AT THE UNIVERSITY PRESS

PREFACE.

THIS volume contains the first Six Books of Euclid's Elements, together with Appendices giving the most important elementary developments of Euclidean Geometry.

The text has been carefully revised, and special attention given to those points which experience has shewn to present difficulties to beginners

In the course of this revision the Enunciations have been altered as little as possible; and, except in Book V., very few departures have been made from Euclid's proofs: in each case changes have been adopted only where the old text has been generally found a cause of difficulty; and such changes are for the most part in favour of well-recognised alternatives

For example, the ambiguity has been removed from the Enunciations of Propositions 18 and 19 of Book I: the fact that Propositions 8 and 26 establish the complete identical equality of the two triangles considered has been strongly urged, and thus the redundant step has been removed from Proposition 34. In Book II Simson's arrangement of Proposition 13 has been abandoned for a well-known alternative proof. In Book III Proposition 25 is not given at length, and its place is taken by a

simple equivalent Propositions 35 and 36 have been treated generally, and it has not been thought necessary to do more than call attention in a note to the special cases. Finally, in Book VI we have adopted an alternative proof of Proposition 7, a theorem which has been too much neglected, owing to the cumbrous form in which it has been usually given.

These are the chief deviations from the ordinary text as regards method and arrangement of proof. They are points familiar as difficulties to most teachers, and to name them indicates sufficiently, without further enumeration, the general principles which have guided our revision.

A few alternative proofs of difficult propositions are given for the convenience of those teachers who care to use them.

With regard to Book V we have established the principal propositions, both from the algebraical and geometrical definitions of ratio and proportion, and we have endeavoured to bring out clearly the distinction between these two modes of treatment.

In compiling the geometrical section of Book V we have followed the system first advocated by the late Professor De Morgan, and here we derived very material assistance from the exposition of the subject given in the text-book of the Association for the Improvement of Geometrical Teaching. To this source we are indebted for the improved and more precise wording of definitions (as given on pages 286, 288 to 291), as well as for the order and substance of most of the propositions which appear between pages 297 and 306. But as we have not (except in the points above mentioned) adhered verbally to the text of the Association, we are anxious, while expressing in the fullest manner our obligation to their work, to exempt the

Association from all responsibility for our treatment of the subject.

One purpose of the book is to gradually familiarise the student with the use of legitimate symbols and abbreviations, for a geometrical argument may thus be thrown into a form which is not only more readily seized by an advanced reader, but is useful as a guide to the way in which Euclid's propositions may be handled in written work. On the other hand, we think it very desirable to defer the introduction of symbols until the beginner has learnt that they can only be properly used in Pure Geometry as abbreviations for verbal argument, and we hope thus to prevent the slovenly and inaccurate habits which are very apt to arise from their employment before this principle is fully recognised.

Accordingly in Book I we have used no contractions or symbols of any kind, though we have introduced verbal alterations into the text wherever it appeared that conciseness or clearness would be gained.

In Book II. abbreviated forms of constantly recurring words are used, and the phrases *therefore* and *is equal to* are replaced by the usual symbols.

In the Third and following Books, and in additional matter throughout the whole, we have employed all such signs and abbreviations as we believe to add to the clearness of the reasoning, care being taken that the symbols chosen are compatible with a rigorous geometrical method, and are recognised by the majority of teachers.

It must be understood that our use of symbols, and the removal of unnecessary verbiage and repetition, by no means implies a desire to secure brevity at all hazards. On the contrary, nothing appears to us more mischievous than an abridgement which is attained by omitting

steps, or condensing two or more steps into one. Such uses spring from the pressure of examinations, but an examination is not, or ought not to be, a mere race, and while we wish to indicate generally in the later books how a geometrical argument may be abbreviated for the purposes of written work, we have not thought well to reduce the propositions to the bare skeleton so often presented to an Examiner. Indeed it does not follow that the form most suitable for the page of a text-book is also best adapted to examination purposes, for the object to be attained in each case is entirely different. The text-book should present the argument in the clearest possible manner to the mind of a reader to whom it is new; the written proposition need only convey to the Examiner the assurance that the proposition has been thoroughly grasped and remembered by the pupil.

From first to last we have kept in mind the undoubted fact that a very small proportion of those who study Elementary Geometry, and study it with profit, are destined to become mathematicians in any real sense; and that to a large majority of students, Euclid is intended to serve not so much as a first lesson in *mathematical* reasoning, as the first, and sometimes the only, model of formal and rigid argument presented in an elementary education.

This consideration has determined not only the full treatment of the earlier Books, but the retention of the formal, if somewhat cumbrous, methods of Euclid in many places where proofs of greater brevity and mathematical elegance are available.

We hope that the additional matter introduced into the book will provide sufficient exercise for pupils whose study of Euclid is preliminary to a mathematical education.

The questions distributed through the text follow very easily from the propositions to which they are attached, and we think that teachers are likely to find in them all that is needed for an average pupil reading the subject for the first time

The Theorems and Examples at the end of each Book contain questions of a slightly more difficult type they have been very carefully classified and arranged, and brought into close connection with typical examples worked out either partially or in full, and it is hoped that this section of the book, on which much thought has been expended, will do something towards removing that extreme want of freedom in solving deductions that is so commonly found even among students who have a good knowledge of the text of Euclid.

In the course of our work we have made ourselves acquainted with most modern English books on Euclidean Geometry: among these we have already expressed our special indebtedness to the text-book recently published by the Association for the Improvement of Geometrical Teaching, and we must also mention the Edition of Euclid's Elements prepared by Mr J S Mackay, whose historical notes and frequent references to original authorities have been of the utmost service to us.

Our treatment of Maxima and Minima on page 239 is based upon suggestions derived from a discussion of the subject which took place at the annual meeting of the Geometrical Association in January 1887.

Of the Riders and Deductions some are original, but the greater part have been drawn from that large store of floating material which has furnished Examination Papers for the last 30 years, and must necessarily form the basis of any elementary collection. Proofs which have been

PREFACE.

found in two or more books without acknowledgement have been regarded as common property. As regards figures, in accordance with a usage not uncommon in recent editions of Euclid, we have made a distinction between given lines and lines of construction. Throughout the book we have italicised those deductions on which we desired to lay special stress as being in themselves important geometrical results. This arrangement we think will be useful to teachers who have little time to devote to riders, or who wish to sketch out a suitable course for revision.

We have in conclusion to tender our thanks to many of our friends for the valuable criticism and advice which we received from them as the book was passing through the press, and especially to the Rev H. C. Watson, of Clifton College, who added to these services much kind assistance in the revision of proof-sheets.

EUCLID'S ELEMENTS.

BOOK I

DEFINITIONS

1 A point is that which has position, but no magnitude

2 A line is that which has length without breadth

The extremities of a line are points, and the intersection of two lines is a point

3 A straight line is that which lies evenly between its extreme points

Any portion cut off from a straight line is called a segment of it

4 A surface is that which has length and breadth, but no thickness

The boundaries of a surface are lines

5 A plane surface is one in which any two points being taken, the straight line between them lies wholly in that surface

A plane surface is frequently referred to simply as a plane

NOTE Euclid regards a point merely as a *mark of position*, and he therefore attaches to it no idea of size and shape

Similarly he considers that the properties of a line arise only from its *length* and *position*, without reference to that minute breadth which every line must really have *if actually drawn*, even though the most perfect instruments are used

The definition of a surface is to be understood in a similar way.

6 A plane angle is the inclination of two straight lines to one another, which meet together, but are not in the same straight line

The point at which the straight lines meet is called the vertex of the angle, and the straight lines themselves the arms of the angle

When several angles are at one point O , any one of them is expressed by three letters, of which the letter that refers to the vertex is put between the other two. Thus if the straight lines OA , OB , OC meet at the point O , the angle contained by the straight lines OA , OB is named the angle AOB or BOA ; and the angle contained by OA , OC is named the angle AOC or COA . Similarly the angle contained by OB , OC is referred to as the angle BOC or COB . But if there be only one angle at a point, it may be expressed by a single letter, as *the angle at O* .

Of the two straight lines OB , OC shewn in the adjoining figure, we recognize that OC is *more inclined* than OB to the straight line OA ; thus we express by saying that the angle AOC is greater than the angle AOB . Thus an angle must be regarded as having *magnitude*.

It should be observed that the angle AOC is the sum of the angles AOB and BOC , and that AOB is the difference of the angles AOC and BOC .

The beginner is cautioned against supposing that the size of an angle is altered either by increasing or diminishing the length of its arms.

[Another view of an angle is recognized in many branches of mathematics, and though not employed by Euclid, it is here given because it furnishes more clearly than any other a conception of what is meant by the *magnitude* of an angle.

Suppose that the straight line OP in the figure is capable of revolution about the point O , like the hand of a watch, but in the opposite direction, and suppose that in this way it has passed successively from the position OA to the positions occupied by OB and OC .

Such a line must have undergone *more turning* in passing from OA to OC , than in passing from OA to OB , and consequently the angle AOC is said to be greater than the angle AOB .

7. When a straight line standing on another straight line makes the adjacent angles equal to one another, each of the angles is called a **right angle**; and the straight line which stands on the other is called a **perpendicular** to it

8. An **obtuse angle** is an angle which is greater than one right angle, but less than two right angles

9. An **acute angle** is an angle which is less than a right angle.

[In the adjoining figure the straight line OB may be supposed to have arrived at its present position, from the position occupied by OA, by revolution about the point O in *either* of the two directions indicated by the arrows: thus two straight lines drawn from a point may be considered as forming *two* angles, (marked (i) and (ii) in the figure) of which the greater (ii) is said to be **reflex**.

If the arms OA, OB are in the same straight line, the angle formed by them on either side is called a **straight angle**]

10. Any portion of a plane surface bounded by one or more lines, straight or curved, is called a **plane figure**

The sum of the bounding lines is called the **perimeter** of the figure

Two figures are said to be equal in area, when they enclose equal portions of a plane surface

11. A **circle** is a plane figure contained by one line, which is called the **circumference**, and is such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another: this point is called the **centre** of the circle

A **radius** of a circle is a straight line drawn from the centre to the circumference

12 A diameter of a circle is a straight line drawn through the centre, and terminated both ways by the circumference

13 A semicircle is the figure bounded by a diameter of a circle and the part of the circumference cut off by the diameter

§ 14 A segment of a circle is the figure bounded by a straight line and the part of the circumference which it cuts off

§ 15 Rectilineal figures are those which are bounded by straight lines

16 A triangle is a plane figure bounded by *three* straight lines

┌ Any one of the angular points of a triangle may be regarded as its vertex, and the opposite side is then called the base

17 A quadrilateral is a plane figure bounded by *four* straight lines

The straight line which joins opposite angular points in a quadrilateral is called a diagonal

18 A polygon is a plane figure bounded by more than four straight lines

19 An equilateral triangle is a triangle whose three sides are equal

20 An isosceles triangle is a triangle two of whose sides are equal

21 A scalene triangle is a triangle which has three unequal sides

22 A right-angled triangle is a triangle which has a right angle

The side opposite to the right angle in a right-angled triangle is called the hypotenuse

23 An obtuse-angled triangle is a triangle which has an obtuse angle

24 An acute-angled triangle is a triangle which has *three* acute angles.

[It will be seen hereafter (Book I Proposition 17) that every triangle must have at least two acute angles]

25 Parallel straight lines are such as, being in the same plane, do not meet, however far they are produced in either direction

26 A Parallelogram is a four-sided figure which has its opposite sides parallel

27 A rectangle is a parallelogram which has one of its angles a right angle

28 A square is a four-sided figure which has all its sides equal and all its angles right angles

[It may easily be shewn that if a quadrilateral has all its sides equal and *one* angle a right angle, then *all* its angles will be right angles]

29 A rhombus is a four-sided figure which has all its sides equal, but its angles are not right angles

30 A trapezium is a four-sided figure which has *two* of its sides parallel

ON THE POSTULATES

In order to effect the *constructions* necessary to the study of geometry, it must be supposed that certain instruments are available, but it has always been held that such instruments should be as few in number, and as simple in character as possible

For the purposes of the first Six Books a *straight ruler* and a pair of compasses are all that are needed, and in the following Postulates, or requests, Euclid demands the use of such instruments, and assumes that they suffice, theoretically as well as practically, to carry out the processes mentioned below

POSTULATES

Let it be granted,

1 That a straight line may be drawn from any one point to any other point

When we draw a straight line from the point A to the point B, we are said to *join* AB

2 That a *finite*, that is to say, a terminated straight line may be produced to any length in that straight line

3 That a circle may be described from any centre, at any distance from that centre, that is, with a radius equal to any finite straight line drawn from the centre

It is important to notice that the Postulates include no means of *direct measurement* hence the straight ruler is not supposed to be *graduated*, and the compasses, in accordance with Euclid's use, are not to be employed for *transferring distances* from one part of a figure to another

ON THE AXIOMS

The science of Geometry is based upon certain simple statements, the truth of which is assumed at the outset to be self-evident.

These self-evident truths, called by Euclid *Common Notions*, are now known as the **AXIOMS**

The necessary characteristics of an Axiom are

- (i) That it should be *self-evident*; that is, that its truth should be immediately accepted without proof
- (ii) That it should be *fundamental*; that is, that its truth should not be derivable from any other truth more simple than itself.
- (iii) That it should supply a basis for the establishment of further truths

These characteristics may be summed up in the following definition.

DEFINITION An Axiom is a self-evident truth, which neither requires nor is capable of proof, but which serves as a foundation for future reasoning

Axioms are of two kinds, *general* and *geometrical*

General Axioms apply to *magnitudes of all kinds* Geometrical Axioms refer exclusively to *geometrical magnitudes*, such as have been already indicated in the definitions

GENERAL AXIOMS.

1. Things which are equal to the same thing are equal to one another
- 2 If equals be added to equals, the wholes are equal.
- 3 If equals be taken from equals, the remainders are equal.
4. If equals be added to unequals, the wholes are unequal, the greater sum being that which includes the greater of the unequals
- 5 If equals be taken from unequals, the remainders are unequal, the greater remainder being that which is left from the greater of the unequals
- 6 Things which are double of the same thing, or of equal things, are equal to one another.
- 7 Things which are halves of the same thing, or of equal things, are equal to one another
- 9 * The whole is greater than its part

* To preserve the classification of general and geometrical axioms, we have placed Euclid's *ninth* axiom before the *eighth*

GEOMETRICAL AXIOMS

8 Magnitudes which can be made to coincide with one another, are equal

This axiom affords the ultimate test of the equality of two geometrical magnitudes. It implies that any line, angle, or figure, may be supposed to be taken up from its position, and without change in size or form, laid down upon a second line, angle, or figure, for the purpose of comparison.

This process is called superposition, and the first magnitude is said to be applied to the other.

10 Two straight lines cannot enclose a space

11 All right angles are equal

[The statement that all right angles are equal, admits of proof, and is therefore perhaps out of place as an Axiom.]

12 If a straight line meet two straight lines so as to make the interior angles on one side of it together less than two right angles, these straight lines will meet if continually produced on the side on which are the angles which are together less than two right angles.

That is to say, if the two straight lines AB and CD are met by the straight line EH at F and G, in such a way that the angles BFG, DGF are together less than two right angles, it is asserted that AB and CD will meet if continually produced in the direction of B and D.

[Axiom 12 has been objected to on the double ground that it cannot be considered self evident, and that its truth may be deduced from simpler principles. It is employed for the first time in the 29th Proposition of Book I, where a short discussion of the difficulty will be found.]

The converse of this Axiom is proved in Book I Proposition 17.]

INTRODUCTORY

Plane Geometry deals with the properties of all lines and figures that may be drawn upon a plane surface

Euclid in his first SIX Books confines himself to the properties of straight lines, rectilineal figures, and circles

The *Definitions* indicate the subject-matter of these books. the *Postulates and Axioms* lay down the fundamental principles which regulate all investigation and argument relating to this subject-matter.

Euclid's method of exposition divides the subject into a number of separate discussions, called **propositions**, each proposition, though in one sense complete in itself, is derived from results previously obtained, and itself leads up to subsequent propositions

Propositions are of two kinds, **Problems** and **Theorems**

A **Problem** proposes to effect some geometrical construction, such as to draw some particular line, or to construct some required figure

A **Theorem** proposes to demonstrate some geometrical truth

A Proposition consists of the following parts

The General Enunciation, the Particular Enunciation, the Construction, and the Demonstration or Proof

(1) The **General Enunciation** is a preliminary statement, describing in general terms the purpose of the proposition

In a *problem* the Enunciation states the construction which it is proposed to effect it therefore names first the **Data**, or things given, secondly the **Quæsitæ**, or things required

In a *theorem* the Enunciation states the property which it is proposed to demonstrate it names first, the **Hypothesis**, or the conditions assumed, secondly, the **Conclusion**, or the assertion to be proved

(ii) The **Particular Enunciation** repeats in special terms the statement already made, and refers it to a diagram, which enables the reader to follow the reasoning more easily

(iii) The **Construction** then directs the drawing of such straight lines and circles as may be required to effect the purpose of a problem, or to prove the truth of a theorem

(iv) Lastly, the **Demonstration** proves that the object proposed in a problem has been accomplished, or that the property stated in a theorem is true

Euclid's reasoning is said to be **Deductive**, because by a connected chain of argument it deduces new truths from truths already proved or admitted

The initial letters Q E F, placed at the end of a problem, stand for *Quod erat Faciendum, which was to be done*

The letters Q E D are appended to a theorem, and stand for *Quod erat Demonstrandum, which was to be proved*

A **Corollary** is a statement the truth of which follows readily from an established proposition, it is therefore appended to the proposition as an inference or deduction, which usually requires no further proof

The following symbols and abbreviations may be employed in writing out the propositions of Book I, though their use is not recommended to beginners

for	therefore,	par ^d (or)	for	parallel,
=	„ is, or are, equal to,	par ^m	„	parallelogram,
∠	„ angle,	sq	„	square,
rt ∠	„ right angle,	rectil	„	rectilineal,
Δ	„ triangle,	st line	„	straight line,
perp	„ perpendicular,	pt	„	point,

and all obvious contractions of words, such as opp, adj, diag, &c, for opposite, adjacent, diagonal, &c

SECTION I.

PROPOSITION I PROBLEM

To describe an equilateral triangle on a given finite straight line

Let AB be the given straight line

It is required to describe an equilateral triangle on AB

Construction From centre A, with radius AB, describe the circle BCD. *Post 3*

From centre B, with radius BA describe the circle ACE *Post 3*

From the point C at which the circles cut one another, draw the straight lines CA and CB to the points A and B *Post 1*

Then shall ABC be an equilateral triangle

Proof. Because A is the centre of the circle BCD, therefore AC is equal to AB *Def. 11.*

And because B is the centre of the circle ACE, therefore BC is equal to BA *Def 11*

But it has been shewn that AC is equal to AB, therefore AC and BC are each equal to AB

But things which are equal to the same thing are equal to one another *Ax 1.*

Therefore AC is equal to BC

Therefore CA, AB, BC are equal to one another.

Therefore the triangle ABC is equilateral;
and it is described on the given straight line AB Q E.F

PROPOSITION 2 PROBLEM

From a given point to draw a straight line equal to a given straight line

Let A be the given point, and BC the given straight line
It is required to draw from the point A a straight line
equal to BC

Construction Join AB, *Post 1*
and on AB describe an equilateral triangle DAB *I 1*
From centre B, with radius BC, describe the circle CGH *Post 3*
Produce DB to meet the circle CGH at G *Post 2*
From centre D, with radius DG, describe the circle GKF
Produce DA to meet the circle GKF at F *Post 2*
Then AF shall be equal to BC

Proof Because B is the centre of the circle CGH,
therefore BC is equal to BG *Def 11*
And because D is the centre of the circle GKF,
therefore DF is equal to DG, *Def 11*
and DA, DB, parts of them are equal, *Def 19*
therefore the remainder AF is equal to the remainder BG *Ax 3*

And it has been shewn that BC is equal to BG,
therefore AF and BC are each equal to BG
But things which are equal to the same thing are equal
to one another *Ax 1*

Therefore AF is equal to BC,
and it has been drawn from the given point A Q E F

[This Proposition is rendered necessary by the restriction, tacitly imposed by Euclid, that compasses shall not be used to transfer distances]

PROPOSITION 3 PROBLEM

From the greater of two given straight lines to cut off a part equal to the less

Let AB and C be the two given straight lines, of which AB is the greater

It is required to cut off from AB a part equal to C

Construction From the point A draw the straight line AD equal to C;
and from centre A, with radius AD, describe the circle DEF,
meeting AB at E.

Post 3

Then AE shall be equal to C

Proof Because A is the centre of the circle DEF,
therefore AE is equal to AD

Def 11.

But C is equal to AD

Constr.

Therefore AE and C are each equal to AD

Therefore AE is equal to C,

and it has been cut off from the given straight line AB

Q E F

EXERCISES

1 On a given straight line describe an isosceles triangle having each of the equal sides equal to a given straight line.

2 On a given base describe an isosceles triangle having each of the equal sides double of the base

3. In the figure of 1 2, if AB is equal to BC, shew that D, the vertex of the equilateral triangle, will fall on the circumference of the circle CGH

Obs Every triangle has six parts, namely its three sides and three angles

Two triangles are said to be equal in all respects, when they can be made to coincide with one another by *superposition* (see note on Axiom 8), and in this case each part of the one is equal to a corresponding part of the other

PROPOSITION 4 THEOREM

If two triangles have two sides of the one equal to two sides of the other, each to each, and have also the angles contained by those sides equal, then shall their bases or third sides be equal, and the triangles shall be equal in area, and their remaining angles shall be equal, each to each, namely those to which the equal sides are opposite that is to say, the triangles shall be equal in all respects

Let ABC , DEF be two triangles, which have the side AB equal to the side DE , the side AC equal to the side DF , and the contained angle BAC equal to the contained angle EDF . Then shall the base BC be equal to the base EF , and the triangle ABC shall be equal to the triangle DEF in area, and the remaining angles shall be equal, each to each, to which the equal sides are opposite,

namely the angle ABC to the angle DEF ,

and the angle ACB to the angle DFE .

For if the triangle ABC be applied to the triangle DEF ,

so that the point A may be on the point D ,

and the straight line AB along the straight line DE ,

then because AB is equal to DE ,

therefore the point B must coincide with the point E . *Hyp*

And because AB falls along DE,
and the angle BAC is equal to the angle EDF, *Hyp*
therefore AC must fall along DF.

And because AC is equal to DF, *Hyp*
therefore the point C must coincide with the point F.

Then B coinciding with E, and C with F,
the base BC must coincide with the base EF,
for if not, two straight lines would enclose a space, which
is impossible. *Ax 10*

Thus the base BC coincides with the base EF, and is
therefore equal to it *Ax 8*

And the triangle ABC coincides with the triangle DEF,
and is therefore equal to it in area *Ax 8*

And the remaining angles of the one coincide with the re-
maining angles of the other, and are therefore equal to them,
namely, the angle ABC to the angle DEF,
and the angle ACB to the angle DFE

That is, the triangles are equal in all respects *Q E D*

NOTE It follows that two triangles which are equal in their
several parts are equal also in *area*, but it should be observed that
equality of area in two triangles does not necessarily imply equality in
their several parts that is to say, triangles may be equal in *area*,
without being of the same *shape*.

Two triangles which are equal in all respects have *identity of form*
and *magnitude*, and are therefore said to be *identically equal*, or
congruent

The following application of Proposition 4 anticipates
the chief difficulty of Proposition 5

In the equal sides AB, AC of an isosceles triangle
ABC, the points X and Y are taken, so that AX
is equal to AY, and BY and CX are joined

Shew that BY is equal to CX

In the two triangles XAC, YAB,

XA is equal to YA, and AC is equal to AB, *Hyp.*
that is, the two sides XA, AC are equal to the two
sides YA, AB, each to each,
and the angle at A, which is contained by these
sides, is common to both triangles

therefore the triangles are equal in all respects,
so that XC is equal to YB

1.4
Q E D

PROPOSITION 5 THEOREM

The angles at the base of an isosceles triangle are equal to one another, and if the equal sides be produced, the angles on the other side of the base shall also be equal to one another

Let ABC be an isosceles triangle, having the side AB equal to the side AC , and let the straight lines AB , AC be produced to D and E

then shall the angle ABC be equal to the angle ACB , and the angle CBD to the angle BCE

Construction In BD take any point F , and from AE the greater cut off AG equal to AF the less I 3

Join FC , GB

Proof Then in the triangles FAC , GAB ,
Const
Hyp
 Because { FA is equal to GA ,
 and AC is equal to AB ,
 also the contained angle at A is common to the
 two triangles,
 therefore the triangle FAC is equal to the triangle GAB in
 all respects, I 4

that is, the base FC is equal to the base GB ,
 and the angle ACF is equal to the angle ABG ,
 also the angle AFC is equal to the angle AGB

Again, because the whole AF is equal to the whole AG ,
 of which the parts AB , AC are equal,
 therefore the remainder BF is equal to the remainder CG *Hyp*

Then in the two triangles BFC, CGB,

Because $\left\{ \begin{array}{ll} \text{BF is equal to CG,} & \text{Proved} \\ \text{and FC is equal to GB,} & \text{Proved} \\ \text{also the contained angle BFC is equal to the} & \\ \text{contained angle CGB,} & \text{Proved} \end{array} \right.$

therefore the triangles BFC, CGB are equal in all respects ;
 so that the angle FBC is equal to the angle GCB,
 and the angle BCF to the angle CBG I. 4.

Now it has been shewn that the whole angle ABG is equal
 to the whole angle ACF,
 and that parts of these, namely the angles CBG, BCF, are
 also equal,
 therefore the remaining angle ABC is equal to the remain-
 ing angle ACB,
 and these are the angles at the base of the triangle ABC
 Also it has been shewn that the angle FBC is equal to the
 angle GCB ;
 and these are the angles on the other side of the base Q E D

✓ COROLLARY *Hence if a triangle is equilateral it is
 also equiangular*

DEFINITION Each of two Theorems is said to be the Con-
 verse of the other, when the hypothesis of each is the conclusion
 of the other.

It will be seen, on comparing the hypotheses and conclusions of
 Props 5 and 6, that each proposition is the converse of the other

NOTE Proposition 6 furnishes the first instance of an *indirect
 method of proof*, frequently used by Euclid. It consists in shewing
 that an absurdity must result from supposing the theorem to be
 otherwise than true. This form of demonstration is known as the
Reductio ad Absurdum, and is most commonly employed in establish-
 ing the converse of some foregoing theorem

✓ It must not be supposed that the converse of a true theorem is
 itself necessarily true for instance, it will be seen from Prop 8, Cor
 that if two triangles have their sides equal, each to each, then their
 angles will also be equal, each to each ; but it may easily be shewn by
 means of a figure that the converse of this theorem is not necessarily
 true

PROPOSITION 6 THEOREM

If two angles of a triangle be equal to one another, then the sides also which subtend, or are opposite to, the equal angles, shall be equal to one another

Let ABC be a triangle, having the angle ABC equal to the angle ACB

then shall the side AC be equal to the side AB

Construction For if AC be not equal to AB, one of them must be greater than the other

If possible, let AB be the greater, and from it cut off BD equal to AC

I 3

Join DC

Proof Then in the triangles DBC ACB,

Because { DB is equal to AC, *Constr*
 and BC is common to both,
 also the contained angle DBC is equal to the
 contained angle ACB, *Hyp*
 therefore the triangle DBC is equal in area to the triangle
 ACB, I 4

the part equal to the whole, which is absurd. *Ax. 9*

Therefore AB is not unequal to AC,

that is, AB is equal to AC.

Q.E.D.

∴ *COROLLARY* Hence if a triangle is equiangular it is also equilateral.

PROPOSITION 7 THEOREM

On the same base, and on the same side of it, there cannot be two triangles having their sides which are terminated at one extremity of the base equal to one another, and likewise those which are terminated at the other extremity equal to one another

If it be possible, on the same base AB, and on the same side of it, let there be two triangles ACB, ADB, having their sides AC, AD, which are terminated at A, equal to one another, and likewise their sides BC, BD, which are terminated at B, equal to one another

CASE I When the vertex of each triangle is without the other triangle

Construction

Join CD

Post. 1

Proof

Then in the triangle ACD,

because AC is equal to AD,

Hyp

therefore the angle ACD is equal to the angle ADC I 5

But the whole angle ACD is greater than its part, the angle BCD,

therefore also the angle ADC is greater than the angle BCD;
still more then is the angle BDC greater than the angle BCD.

Again, in the triangle BCD,

because BC is equal to BD,

Hyp

therefore the angle BDC is equal to the angle BCD I 5.

but it was shewn to be greater, which is impossible

CASE II When one of the vertices, as D, is within the other triangle ACB

Construction As before, join CD, *Post 1*
and produce AC, AD to E and F *Post 2*

Then in the triangle ACD, because AC is equal to AD, *Hyp*
therefore the angles ECD, FDC, on the other side of the
base, are equal to one another I 5

But the angle ECD is greater than its part, the angle BCD,
therefore the angle FDC is also greater than the angle
BCD
still more then is the angle BDC greater than the angle
BCD

Again, in the triangle BCD,
because BC is equal to BD,

therefore the angle BDC is equal to the angle BCD *Hyp*
I 5
but it has been shewn to be greater, which is impossible

The case in which the vertex of one triangle is on a side of the other needs no demonstration

Therefore AC cannot be equal to AD, and at the same
time, BC equal to BD Q E D

NOTE The sides AC, AD are called conterminous sides, similarly the sides BC, BD are conterminous

PROPOSITION 8 THEOREM

If two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise their bases equal, then the angle which is contained by the two sides of the one shall be equal to the angle which is contained by the two sides of the other.

Let ABC , DEF be two triangles, having the two sides BA , AC equal to the two sides ED , DF , each to each, namely BA to ED , and AC to DF , and also the base BC equal to the base EF

then shall the angle BAC be equal to the angle EDF

Proof For if the triangle ABC be applied to the triangle DEF , so that the point B may be on E , and the straight line BC along EF ,

then because BC is equal to EF , *Hyp*

therefore the point C must coincide with the point F

Then, BC coinciding with EF ,

it follows that BA and AC must coincide with ED and DF for if not, they would have a different situation, as EG , GF then, on the same base and on the same side of it there would be two triangles having their *contiguous* sides equal

But this is impossible I 7

Therefore the sides BA , AC coincide with the sides ED , DF That is, the angle BAC coincides with the angle EDF , and is therefore equal to it A2 8

Q E D

NOTE In this Proposition the three sides of one triangle are given equal respectively to the three sides of the other, and from this it is shewn that the two triangles may be made to coincide with one another.

Hence we are led to the following important Corollary

∫ **COROLLARY** *If in two triangles the three sides of the one are equal to the three sides of the other, each to each, then the triangles are equal in all respects.*

The following proof of Prop 8 is worthy of attention as it is independent of Prop 7, which frequently presents difficulty to a beginner

PROPOSITION 8 ALTERNATIVE PROOF

Let ABC and DEF be two triangles, which have the sides BA , AC equal respectively to the sides ED , DF , and the base BC equal to the base EF

then shall the angle BAC be equal to the angle EDF

For apply the triangle ABC to the triangle DEF , so that B may fall on E , and BC along EF , and so that the point A may be on the side of EF remote from D ,

then C must fall on F , since BC is equal to EF

Let $A'EF$ be the new position of the triangle ABC

If neither DF , FA' nor DE , EA' are in one straight line,
join DA'

CASE I When DA' intersects EF

Then because ED is equal to EA' ,

therefore the angle EDA' is equal to the angle $EA'D$ 1 5

Again because FD is equal to FA' ,

therefore the angle FDA' is equal to the angle $FA'D$ 1 5

Hence the whole angle EDF is equal to the whole angle $EA'F$,
that is, the angle EDF is equal to the angle BAC

Two cases remain which may be dealt with in a similar manner namely,

CASE II When DA' meets EF produced

CASE III When one pair of sides, as DF , FA' , are in one straight line

PROPOSITION 9 PROBLEM

To bisect a given angle, that is, to divide it into two equal parts

Let BAC be the given angle.
it is required to bisect it

Construction. In AB take any point D,
and from AC cut off AE equal to AD I 3

Join DE,

and on DE, on the side remote from A, describe an equilateral triangle DEF I 1

Join AF.

Then shall the straight line AF bisect the angle BAC.

Proof For in the two triangles DAF, EAF,

DA is equal to EA,

Constr.

and AF is common to both,

Because { and the third side DF is equal to the third side EF,

Def 19

therefore the angle DAF is equal to the angle EAF I 8

Therefore the given angle BAC is bisected by the straight line AF Q E F

EXERCISES

1. If in the above figure the equilateral triangle DFE were described on the same side of DE as A, what different cases would arise? And under what circumstances would the construction fail?

2 In the same figure, shew that AF also bisects the angle DFE

3 Divide an angle into four equal parts

PROPOSITION 10 PROBLEM

To bisect a given finite straight line, that is, to divide it into two equal parts

Let AB be the given straight line
it is required to divide it into two equal parts

Constr On AB describe an equilateral triangle ABC, 1 1
and bisect the angle ACB by the straight line CD, meeting
AB at D 1 9

Then shall AB be bisected at the point D

Proof For in the triangles ACD, BCD,
AC is equal to BC, *Def 19*
and CD is common to both,
Because { also the contained angle ACD is equal to the con-
tained angle BCD, *Constr*
Therefore the triangles are equal in all respects
so that the base AD is equal to the base BD 1 4
Therefore the straight line AB is bisected at the point D
Q E F

EXERCISES

1 Shew that the straight line which bisects the vertical angle of an isosceles triangle, also bisects the base

2 On a given base describe an isosceles triangle such that the sum of its equal sides may be equal to a given straight line

PROPOSITION 11 PROBLEM

To draw a straight line at right angles to a given straight line, from a given point in the same

Let AB be the given straight line, and C the given point in it

It is required to draw from the point C a straight line at right angles to AB

Construction In AC take any point D,
and from CB cut off CE equal to CD I 3
On DE describe the equilateral triangle DFE I 1
Join CF

Then shall the straight line CF be at right angles to AB

Proof For in the triangles DCF, ECF,
DC is equal to EC, *Constr*
and CF is common to both,
Because { and the third side DF is equal to the third side
EF *Def 19*

Therefore the angle DCF is equal to the angle ECF I 8
and these are adjacent angles

But when a straight line, standing on another straight line, makes the adjacent angles equal to one another, each of these angles is called a right angle, *Def. 7*

therefore each of the angles DCF, ECF is a right angle

Therefore CF is at right angles to AB,
and has been drawn from a point C in it Q E F

EXERCISE

In the figure of the above proposition, shew that any point in FC, or FC produced, is equidistant from D and E

PROPOSITION 12 PROBLEM.

To draw a straight line perpendicular to a given straight line of unlimited length, from a given point without it

Let AB be the given straight line, which may be produced in either direction, and let C be the given point without it

It is required to draw from the point C a straight line perpendicular to AB

Construction On the side of AB remote from C take any point D,
and from centre C, with radius CD, describe the circle FDG,
meeting AB at F and G

Post 3

Bisect FG at H,

I 10

and join CH

Then shall the straight line CH be perpendicular to AB

Join CF and CG

Proof Then in the triangles FHC, GHC,

Because { FH is equal to GH, *Constr*
and HC is common to both,
and the third side CF is equal to the third side
CG, being radii of the circle FDG, *Def 11*
therefore the angle CHF is equal to the angle CHG, *I 8*
and these are adjacent angles

But when a straight line, standing on another straight line, makes the adjacent angles equal to one another, each of these angles is called a right angle, and the straight line which stands on the other is called a perpendicular to it

Therefore CH is a perpendicular drawn to the given straight line AB from the given point C without it Q E F

NOTE The given straight line AB must be of unlimited length, that is, it must be capable of production to an indefinite length in either direction, to ensure its being intersected in two points by the circle FDG

EXERCISES ON PROPOSITIONS 1 TO 12.

1. Shew that the straight line which joins the vertex of an isosceles triangle to the middle point of the base is perpendicular to the base.

2. Shew that the straight lines which join the extremities of the base of an isosceles triangle to the middle points of the opposite sides, are equal to one another

3 Two given points in the base of an isosceles triangle are equidistant from the extremities of the base. shew that they are also equidistant from the vertex

4 If the opposite sides of a quadrilateral are equal, shew that the opposite angles are also equal

5. Any two isosceles triangles XAB , YAB stand on the same base AB shew that the angle XAY is equal to the angle $XB Y$, and that the angle AXY is equal to the angle BXY .

6. Shew that the opposite angles of a rhombus are bisected by the diagonal which joins them

7 Shew that the straight lines which bisect the base angles of an isosceles triangle form with the base a triangle which is also isosceles

8 ABC is an isosceles triangle having AB equal to AC , and the angles at B and C are bisected by straight lines which meet at O shew that OA bisects the angle BAC .

9. Shew that the triangle formed by joining the middle points of the sides of an equilateral triangle is also equilateral.

10 The equal sides BA , CA of an isosceles triangle BAC are produced beyond the vertex A to the points E and F , so that AE is equal to AF , and FB , EC are joined. shew that FB is equal to EC

11 Shew that the diagonals of a rhombus bisect one another at right angles

12 In the equal sides AB , AC of an isosceles triangle ABC two points X and Y are taken, so that AX is equal to AY , and CX and BY are drawn intersecting in O shew that

- (i) the triangle BOC is isosceles,
- (ii) AO bisects the vertical angle BAC ,
- (iii) AO , if produced, bisects BC at right angles

13 Describe an isosceles triangle, having given the base and the length of the perpendicular drawn from the vertex to the base.

14 In a given straight line find a point that is equidistant from two given points

In what case is this impossible?

PROPOSITION 13 THEOREM

If one straight line stand upon another straight line, then the adjacent angles shall be either two right angles, or together equal to two right angles

Let the straight line AB stand upon the straight line DC then the adjacent angles DBA, ABC shall be either two right angles, or together equal to two right angles

CASE I. For if the angle DBA is equal to the angle ABC, each of them is a right angle *Def 7*

CASE II But if the angle DBA is not equal to the angle ABC,

from B draw BE at right angles to CD i 11

Proof Now the angle DBA is made up of the two angles DBE, EBA,

to each of these equals add the angle ABC,
then the two angles DBA, ABC are together equal to the
three angles DBE, EBA, ABC *Ax. 2*

Again, the angle EBC is made up of the two angles EBA, ABC,

to each of these equals add the angle DBE
Then the two angles DBE, EBC are together equal to the
three angles DBE, EBA, ABC *Ax. 2*

But the two angles DBA, ABC have been shewn to be equal to the same three angles,
therefore the angles DBA, ABC are together equal to the
angles DBE, EBC *Ax. 1*

But the angles DBE, EBC are two right angles, *Constr*
therefore the angles DBA, ABC are together equal to two
right angles Q E D

DEFINITIONS

(1) The **complement** of an acute angle is its *defect from* a right angle, that is, the angle by which it falls short of a right angle

Thus two angles are **complementary**, when their sum is a right angle

(11) The **supplement** of an angle is its *defect from* two right angles, that is, the angle by which it falls short of two right angles

Thus two angles are **supplementary**, when their sum is two right angles

COROLLARY *Angles which are complementary or supplementary to the same angle are equal to one another*

EXERCISES

1 If the two exterior angles formed by producing a side of a triangle both ways are equal, shew that the triangle is isosceles

2 *The bisectors of the adjacent angles which one straight line makes with another contain a right angle*

NOTE In the adjoining figure AOB is a given angle, and one of its arms AO is produced to C the adjacent angles AOB, BOC are bisected by OX, OY

Then OX and OY are called respectively the **internal** and **external bisectors** of the angle AOB

Hence Exercise 2 may be thus enunciated

The internal and external bisectors of an angle are at right angles to one another

3 Shew that the angles AOX and COY are complementary

4 Shew that the angles BOX and COX are supplementary, and also that the angles AOY and BOY are supplementary

PROPOSITION 14 THEOREM

If, at a point in a straight line, two other straight lines, on opposite sides of it, make the adjacent angles together equal to two right angles, then these two straight lines shall be in one and the same straight line

At the point B in the straight line AB, let the two straight lines BC, BD, on the opposite sides of AB, make the adjacent angles ABC, ABD together equal to two right angles

then BD shall be in the same straight line with BC

Proof For if BD be not in the same straight line with BC, if possible, let BE be in the same straight line with BC

Then because AB meets the straight line CBE, therefore the adjacent angles CBA, ABE are together equal to two right angles I 13

But the angles CBA, ABD are also together equal to two right angles Hyp

Therefore the angles CBA, ABE are together equal to the angles CBA, ABD Ax. 11

From each of these equals take the common angle CBA, then the remaining angle ABE is equal to the remaining angle ABD, the part equal to the whole, which is impossible

Therefore BE is not in the same straight line with BC

And in the same way it may be shewn that no other line but BD can be in the same straight line with BC

Therefore BD is in the same straight line with BC Q.E.D.

EXERCISE

ABCD is a rhombus, and the diagonal AC is bisected at O. If O is joined to the angular points B and D; shew that OB and OD are in one straight line

Obs When two straight lines intersect at a point, four angles are formed; and any two of these angles *which are not adjacent*, are said to be *vertically opposite* to one another

PROPOSITION 15 THEOREM

If two straight lines intersect one another, then the vertically opposite angles shall be equal

Let the two straight lines AB, CD cut one another at the point E

then shall the angle AEC be equal to the angle DEB,
and the angle CEB to the angle AED

Proof. Because AE makes with CD the adjacent angles CEA, AED,

therefore these angles are together equal to two right angles I 13

Again, because DE makes with AB the adjacent angles AED, DEB,

therefore these also are together equal to two right angles
Therefore the angles CEA, AED are together equal to the angles AED, DEB

From each of these equals take the common angle AED,
then the remaining angle CEA is equal to the remaining angle DEB Ax 3.

In a similar way it may be shewn that the angle CEB is equal to the angle AED. Q E D

COROLLARY 1 *From this it is manifest that, if two straight lines cut one another, the angles which they make at the point where they cut, are together equal to four right angles*

COROLLARY 2 *Consequently, when any number of straight lines meet at a point, the sum of the angles made by consecutive lines is equal to four right angles*

PROPOSITION 16 THEOREM

If one side of a triangle be produced, then the exterior angle shall be greater than either of the interior opposite angles

Let ABC be a triangle, and let one side BC be produced to D then shall the exterior angle ACD be greater than either of the interior opposite angles CBA, BAC

Construction Bisect AC at E I 10
 Join BE, and produce it to F, making EF equal to BE I 3
 Join FC

Proof Then in the triangles AEB, CEF,
 Because { AE is equal to CE, *Constr*
 { and EB to EF, *Constr*
 { also the angle AEB is equal to the vertically
 { opposite angle CEF, I 15
 therefore the triangle AEB is equal to the triangle CEF in
 all respects I 4
 so that the angle BAE is equal to the angle ECF

But the angle ECD is greater than its part, the angle ECF,
 therefore the angle ECD is greater than the angle BAE,
 that is, the angle ACD is greater than the angle BAC

In a similar way, if BC be bisected, and the side AC produced to G, it may be shewn that the angle BCG is greater than the angle ABC

But the angle BCG is equal to the angle ACD I 15
 therefore also the angle ACD is greater than the angle ABC

Q E D.

PROPOSITION 17 THEOREM

Any two angles of a triangle are together less than two right angles

Let ABC be a triangle: then shall any two of its angles, as ABC, ACB, be together less than two right angles

Construction Produce the side BC to D.

Proof. Then because ACD is an exterior angle of the triangle ABC,

therefore it is greater than the interior opposite angle ABC I 16.

To each of these add the angle ACB -

then the angles ACD, ACB are together greater than the angles ABC, ACB. Ax 4

But the adjacent angles ACD, ACB are together equal to two right angles. I 13

Therefore the angles ABC, ACB are together less than two right angles

Similarly it may be shewn that the angles BAC, ACB, as also the angles CAB, ABC, are together less than two right angles. Q E D

NOTE. It follows from this Proposition that *every triangle must have at least two acute angles* for if one angle is obtuse, or a right angle, each of the other angles must be less than a right angle

EXERCISES

1. Enunciate this Proposition so as to shew that it is the converse of Axiom 12

2. If any side of a triangle is produced both ways, the exterior angles so formed are together greater than two right angles

3. Shew how a proof of Proposition 17 may be obtained by joining each vertex in turn to any point in the opposite side.

PROPOSITION 18 THEOREM

If one side of a triangle be greater than another, then the angle opposite to the greater side shall be greater than the angle opposite to the less

Let ABC be a triangle, in which the side AC is greater than the side AB

then shall the angle ABC be greater than the angle ACB

Construction From AC, the greater, cut off a part AD equal to AB I 3

Join BD

Proof Then in the triangle ABD,
because AB is equal to AD,

therefore the angle ABD is equal to the angle ADB I 5

But the exterior angle ADB of the triangle BDC is greater than the interior opposite angle DCB, that is, greater than the angle ACB I 16

Therefore also the angle ABD is greater than the angle ACB, still more then is the angle ABC greater than the angle ACB Q E D

Euclid enunciated Proposition 18 as follows -

The greater side of every triangle has the greater angle opposite to it

[This form of enunciation is found to be a common source of difficulty with beginners, who fail to distinguish what is *assumed* in it and what is to be *proved*]

[For Exercises see page 48]

PROPOSITION 19. THEOREM.

If one angle of a triangle be greater than another, then the side opposite to the greater angle shall be greater than the side opposite to the less.

Let ABC be a triangle in which the angle ABC is greater than the angle ACB.

then shall the side AC be greater than the side AB

Proof For if AC be not greater than AB,
it must be either equal to, or less than AB

But AC is not equal to AB,
for then the angle ABC would be equal to the angle ACB, 1 5
but it is not *Hyp*

Neither is AC less than AB,
for then the angle ABC would be less than the angle ACB, 1 18
but it is not *Hyp*

Therefore AC is neither equal to, nor less than AB.

That is, AC is greater than AB Q E D.

NOTE The mode of demonstration used in this Proposition is known as the **Proof by Exhaustion**. It is applicable to cases in which one of certain mutually exclusive suppositions must necessarily be true, and it consists in shewing the falsity of each of these suppositions in turn *with one exception*. hence the truth of the remaining supposition is inferred

Euclid enunciated Proposition 19 as follows

The greater angle of every triangle is subtended by the greater side, or, has the greater side opposite to it

[For Exercises see page 38]

PROPOSITION 20 THEOREM

Any two sides of a triangle are together greater than the third side

Let ABC be a triangle
then shall any two of its sides be together greater than the third side

namely, BA, AC, shall be greater than CB,
AC, CB greater than BA,
and CB, BA greater than AC

Construction Produce BA to the point D, making AD equal to AC I 3

Join DC

Proof Then in the triangle ADC,
because AD is equal to AC, *Constr.*
therefore the angle ACD is equal to the angle ADC. I 5.
But the angle BCD is greater than the angle ACD, *Ax. 9.*
therefore also the angle BCD is greater than the angle ADC,
that is, than the angle BDC

And in the triangle BCD,
because the angle BCD is greater than the angle BDC, *Pr*
therefore the side BD is greater than the side CB I 19

But BA and AC are together equal to BD,
therefore BA and AC are together greater than CB

Similarly it may be shewn

that AC, CB are together greater than BA,
and CB, BA are together greater than AC Q. E. D.

PROPOSITION 21. THEOREM

If from the ends of a side of a triangle, there be drawn two straight lines to a point within the triangle, then these straight lines shall be less than the other two sides of the triangle, but shall contain a greater angle

Let ABC be a triangle, and from B, C , the ends of the side BC , let the two straight lines BD, CD be drawn to a point D within the triangle.

then (1) BD and DC shall be together less than BA and AC ,

(2) the angle BDC shall be greater than the angle BAC

Construction. Produce BD to meet AC in E .

Proof. (1) In the triangle BAE , the two sides BA, AE are together greater than the third side BE : I. 20.

to each of these add EC ;

then BA, AC are together greater than BE, EC Ax. 4.

Again, in the triangle DEC , the two sides DE, EC are together greater than DC I. 20.

to each of these add BD ,

then BE, EC are together greater than BD, DC .

But it has been shewn that BA, AC are together greater than BE, EC .

still more then are BA, AC greater than BD, DC .

(2) Again, the exterior angle BDC of the triangle DEC is greater than the interior opposite angle DEC , I. 16

and the exterior angle DEC of the triangle BAE is greater than the interior opposite angle BAE , that is, than the angle BAC , I. 16

still more then is the angle BDC greater than the angle BAC

Q E D

EXERCISES

ON PROPOSITIONS 18 AND 19

1 The hypotenuse is the greatest side of a right angled triangle

2 If two angles of a triangle are equal to one another, the sides also, which subtend the equal angles, are equal to one another. Prop 6. Prove this indirectly by using the result of Prop 18

3 BC, the base of an isosceles triangle ABC, is produced to any point D, shew that AD is greater than either of the equal sides

4 If in a quadrilateral the greatest and least sides are opposite to one another, then each of the angles adjacent to the least side is greater than its opposite angle

5 In a triangle ABC, if AC is not greater than AB, shew that any straight line drawn through the vertex A and terminated by the base BC, is less than AB

6 ABC is a triangle, in which OB, OC bisect the angles ABC, ACB respectively shew that, if AB is greater than AC, then OB is greater than OC

ON PROPOSITION 20

7 The difference of any two sides of a triangle is less than the third side

8. In a quadrilateral, if two opposite sides which are not parallel are produced to meet one another, shew that the perimeter of the greater of the two triangles so formed is greater than the perimeter of the quadrilateral.

9 The sum of the distances of any point from the three angular points of a triangle is greater than half its perimeter,

10 The perimeter of a quadrilateral is greater than the sum of its diagonals.

11 Obtain a proof of Proposition 20 by bisecting an angle by a straight line which meets the opposite side.

ON PROPOSITION 21

12 In Proposition 21 shew that the angle BDC is greater than the angle BAC by joining AD, and producing it towards the base

13 The sum of the distances of any point within a triangle from its angular points is less than the perimeter of the triangle

PROPOSITION 22 PROBLEM

To describe a triangle having its sides equal to three given straight lines, any two of which are together greater than the third.

Let A, B, C be the three given straight lines, of which any two are together greater than the third

It is required to describe a triangle of which the sides shall be equal to A, B, C

Construction Take a straight line DE terminated at the point D, but unlimited towards E

Make DF equal to A, FG equal to B, and GH equal to C

From centre F, with radius FD, describe the circle DLK
From centre G with radius GH, describe the circle MHK,
cutting the former circle at K

Join FK, GK

Then shall the triangle KFG have its sides equal to the three straight lines A, B, C

Proof Because F is the centre of the circle DLK,
therefore FK is equal to FD *Def. 11*
but FD is equal to A, *Constr.*
therefore also FK is equal to A *Ax 1.*

Again, because G is the centre of the circle MHK,
therefore GK is equal to GH *Def 11*
but GH is equal to C, *Constr*
therefore also GK is equal to C *Ax 1*
And FG is equal to B *Constr*

Therefore the triangle KFG has its sides KF, FG, GK equal respectively to the three given lines A, B, C *Q E F*

EXERCISE

On a given base describe a triangle, whose remaining sides shall be equal to two given straight lines. Point out how the construction fails, if any one of the three given lines is greater than the sum of the other two

PROPOSITION 23 PROBLEM

At a given point in a given straight line, to make an angle equal to a given angle

Let AB be the given straight line, and A the given point in it, and let DCE be the given angle

It is required to draw from A a straight line making with AB an angle equal to the given angle DCE

Construction In CD, CE take any points D and E, and join DE

From AB cut off AF equal to CD I 3

On AF describe the triangle FAG, having the remaining sides AG, GF equal respectively to CE, ED. I 22

Then shall the angle FAG be equal to the angle DCE

Proof For in the triangles FAG, DCE,

Because {	FA is equal to DC,	<i>Constr</i>
	and AG is equal to CE,	<i>Constr</i>
	and the base FG is equal to the base DE	<i>Constr</i>

therefore the angle FAG is equal to the angle DCE. I 8

That is, AG makes with AB, at the given point A, an angle equal to the given angle DCE. Q.E.F

PROPOSITION 24

If two triangles have two sides of the one equal to two sides of the other, each to each, but the angle contained by the two sides of one greater than the angle contained by the corresponding sides of the other; then the base of that which has the greater angle shall be greater than the base of the other

Let ABC , DEF be two triangles, in which the two sides BA , AC are equal to the two sides ED , DF , each to each, but the angle BAC greater than the angle EDF :

then shall the base BC be greater than the base EF

* Of the two sides DE , DF , let DE be that which is not greater than DF

Construction At the point D , in the straight line ED , and on the same side of it as DF , make the angle EDG equal to the angle BAC I 23.

Make DG equal to DF or AC ; I 3
and join EG , GF .

Proof Then in the triangles BAC , EDG ,
 Because { BA is equal to ED , *Hyp.*
 { and AC is equal to DG , *Constr.*
 { also the contained angle BAC is equal to the
 { contained angle EDG ; *Constr.*
 Therefore the triangle BAC is equal to the triangle EDG in
 all respects. I 4

so that the base BC is equal to the base EG

* See note on the next page

Again, in the triangle FDG,
because DG is equal to DF,
therefore the angle DFG is equal to the angle DGF, 1 5
but the angle DGF is greater than the angle EGF,
therefore also the angle DFG is greater than the angle EGF,
still more then is the angle EFG greater than the angle EGF

And in the triangle EFG,
because the angle EFG is greater than the angle EGF,
therefore the side EG is greater than the side EF, 1 19
but EG was shewn to be equal to BC,
therefore BC is greater than EF Q E D

* This condition was inserted by Simson to ensure that, in the complete construction, the point F should fall *below* EG. Without this condition it would be necessary to consider three cases for F might fall *above*, or *upon*, or *below* EG, and each figure would require separate proof.

We are however scarcely at liberty to employ Simson's condition without *proving* that it fulfils the object for which it was introduced.

This may be done as follows

Let EG, DF, produced if necessary, intersect at K

Then, since DE is not greater than DF,

that is, since DE is not greater than DG,

therefore the angle DGE is not greater than the angle DEG 1 18

But the exterior angle DKG is greater than the angle DEK 1 16

therefore the angle DKG is greater than the angle DGK

Hence DG is greater than DK 1 19.

But DG is equal to DF,

therefore DF is greater than DK

So that the point F must fall *below* EG

Or the following method may be adopted

PROPOSITION 24. [ALTERNATIVE PROOF.]

In the triangles ABC , DEF ,
let BA be equal to ED ,
and AC equal to DF ,
but let the angle BAC be greater than
the angle EDF :
then shall the base BC be greater than
the base EF .

For apply the triangle DEF to the
triangle ABC , so that D may fall on A ,
and DE along AB .

then because DE is equal to AB ,
therefore E must fall on B

And because the angle EDF is less than the angle BAC ,
therefore DF must fall between AB and AC .

Hyp

Let DF occupy the position AG

CASE I. If G falls on BC .

Then G must be between B and C
therefore BC is greater than BG .

But BG is equal to EF
therefore BC is greater than EF

CASE II. If G does not fall on BC
Bisect the angle CAG by the straight line AK
which meets BC in K

I 9

Join GK

Hyp

Then in the triangles GAK , CAK ,
Because $\left\{ \begin{array}{l} GA \text{ is equal to } CA, \\ \text{and } AK \text{ is common to both;} \\ \text{and the angle } GAK \text{ is equal to the} \\ \text{angle } CAK; \end{array} \right.$
therefore GK is equal to CK

Constr
I. 4

But in the triangle BKG ,
the two sides BK , KG are together greater than the third side BG , I 20
that is, BK , KC are together greater than BG ,
therefore BC is greater than BG , or EF .

Q E D

PROPOSITION 25. THEOREM

If two triangles have two sides of the one equal to two sides of the other, each to each, but the base of one greater than the base of the other, then the angle contained by the sides of that which has the greater base, shall be greater than the angle contained by the corresponding sides of the other.

Let ABC , DEF be two triangles which have the two sides BA , AC equal to the two sides ED , DF , each to each, but the base BC greater than the base EF :

then shall the angle BAC be greater than the angle EDF .

Proof For if the angle BAC be not greater than the angle EDF , it must be either equal to, or less than the angle EDF

But the angle BAC is not equal to the angle EDF ,
for then the base BC would be equal to the base EF , I. 4
but it is not *Hyp.*

Neither is the angle BAC less than the angle EDF ,
for then the base BC would be less than the base EF , I. 24
but it is not *Hyp.*

Therefore the angle BAC is neither equal to, nor less than the angle EDF ,

that is, the angle BAC is greater than the angle EDF $Q.E.D.$

EXERCISE.

In a triangle ABC , the vertex A is joined to X , the middle point of the base BC , shew that the angle AXB is obtuse or acute, according as AB is greater or less than AC

PROPOSITION 26 THEOREM

If two triangles have two angles of the one equal to two angles of the other, each to each, and a side of one equal to a side of the other, these sides being either adjacent to the equal angles, or opposite to equal angles in each; then shall the triangles be equal in all respects

CASE I When the equal sides are *adjacent* to the equal angles in the two triangles.

Let ABC , DEF be two triangles, which have the angles ABC , ACB , equal to the two angles DEF , DFE , each to each, and the side BC equal to the side EF .

then shall the triangle ABC be equal to the triangle DEF in all respects;

that is, AB shall be equal to DE , and AC to DF ,
and the angle BAC shall be equal to the angle EDF .

For if AB be not equal to DE , one must be greater than the other. If possible, let AB be greater than DE

Construction. From BA cut off BG equal to ED , I. 3.
and join GC .

Proof Then in the two triangles GBC , DEF ,

Because	{	GB is equal to DE,	<i>Constr.</i>
		and BC to EF,	<i>Hyp</i>
		also the contained angle GBC is equal to the contained angle DEF ;	<i>Hyp.</i>

therefore the triangles are equal in all respects; I. 4

so that the angle GCB is equal to the angle DFE

But the angle ACB is equal to the angle DFE ; *Hyp*

therefore also the angle GCB is equal to the angle ACB , *Ax 1.*

the part equal to the whole, which is impossible

Therefore AB is not unequal to DE,
that is, AB is equal to DE.

Hence in the triangles ABC, DEF,
AB is equal to DE,

and BC is equal to EF,

Because { also the contained angle ABC is equal to the
contained angle DEF, *Proved*
Hyp
therefore the triangles are equal in all respects. *Hyp*
I 4.
so that the side AC is equal to the side DF,
and the angle BAC to the angle EDF Q E D

CASE II When the equal sides are *opposite* to equal
angles in the two triangles

Let ABC, DEF be two triangles which have the angles
ABC, ACB equal to the angles DEF, DFE, each to each,
and the side AB equal to the side DE
then shall the triangles ABC, DEF be equal in all respects,
that is, BC shall be equal to EF, and AC to DF,
and the angle BAC shall be equal to the angle EDF

For if BC be not equal to EF, one must be greater than the other. If possible, let BC be greater than EF

Construction From BC cut off BH equal to EF, I 3
and join AH

Proof. Then in the triangles ABH, DEF,
Because { AB is equal to DE, *Hyp*
and BH to EF, *Constr.*
also the contained angle ABH is equal to the
contained angle DEF, *Hyp*
therefore the triangles are equal in all respects, I 4
so that the angle AHB is equal to the angle DFE

But the angle DFE is equal to the angle ACB; *Hyp*
therefore the angle AHB is equal to the angle ACB, *Ax. 1*
that is, an exterior angle of the triangle ACH is equal to
an interior opposite angle, which is impossible I 16

Therefore BC is not unequal to EF,
that is, BC is equal to EF.

Hence in the triangles ABC, DEF,
Because { AB is equal to DE, *Hyp*
and BC is equal to EF; *Proved*
also the contained angle ABC is equal to the
contained angle DEF; *Hyp.*
therefore the triangles are equal in all respects, I 4
so that the side AC is equal to the side DF,
and the angle BAC to the angle EDF

Q E D

 COROLLARY. In both cases of this Proposition it is seen that the triangles may be made to coincide with one another, and they are therefore equal in area

ON THE IDENTICAL EQUALITY OF TRIANGLES.

At the close of the first section of Book I, it is worth while to call special attention to those Propositions (*viz.* Props. 4, 8, 26) which deal with the *identical equality* of two triangles.

The results of these Propositions may be summarized thus

Two triangles are equal to one another in all respects, when the following parts in each are equal, each to each.

- | | |
|---|---------------------|
| 1. Two sides, and the included angle. | <i>Prop. 4.</i> |
| 2. The three sides | <i>Prop 8, Cor.</i> |
| 3. (a) Two angles, and the adjacent side. | } <i>Prop 26</i> |
| (b) Two angles, and the side opposite one of them | |

From this the beginner will perhaps surmise that two triangles may be shewn to be equal in all respects, when they have *three parts* equal, each to each, but to this statement two obvious exceptions must be made.

(i) When in two triangles the *three angles* of one are equal to the *three angles* of the other, each to each, it does *not* necessarily follow that the triangles are equal in all respects.

(ii) When in two triangles two sides of the one are equal to two sides of the other, each to each, and one angle equal to one angle, these not being the angles included by the equal sides; the triangles are *not* necessarily equal in all respects.

In these cases a further condition must be added to the hypothesis, before we can assert the identical equality of the two triangles.

[See Theorems and Exercises on Book I, Ex. 13, Page 92]

We observe that in each of the three cases already proved of identical equality in two triangles, namely in Propositions 4, 8, 26, it is shewn that the triangles may be made to *coincide with one another*; so that they are equal in *area*, as in all other respects. Euclid however restricted himself to the use of Prop. 4, when he required to deduce the equality in *area* of two triangles from the equality of certain of their parts.

This restriction has been abandoned in the present text-book. [See note to Prop 34]

EXERCISES ON PROPOSITIONS 12—26

1 If BX and CY , the bisectors of the angles at the base BC of an isosceles triangle ABC , meet the opposite sides in X and Y , shew that the triangles YBC , XCB are equal in all respects

2 Shew that the perpendiculars drawn from the extremities of the base of an isosceles triangle to the opposite sides are equal.

3 Any point on the bisector of an angle is equidistant from the arms of the angle

4 Through O , the middle point of a straight line AB , any straight line is drawn, and perpendiculars AX and BY are dropped upon it from A and B shew that AX is equal to BY

5 If the bisector of the vertical angle of a triangle is at right angles to the base, the triangle is isosceles

6. The perpendicular is the shortest straight line that can be drawn from a given point to a given straight line, and of others, that which is nearer to the perpendicular is less than the more remote, and two, and only two equal straight lines can be drawn from the given point to the given straight line, one on each side of the perpendicular

7 From two given points on the same side of a given straight line, draw two straight lines, which shall meet in the given straight line and make equal angles with it

Let AB be the given straight line, and P, Q the given points

It is required to draw from P and Q to a point in AB , two straight lines that shall be equally inclined to AB

Construction From P draw PH perpendicular to AB produce PH to P' , making HP' equal to PH Draw QP' , meeting AB in K Join PK

Then PK, QK shall be the required lines [Supply the proof]

8 In a given straight line find a point which is equidistant from two given intersecting straight lines In what case is this impossible?

9 Through a given point draw a straight line such that the perpendiculars drawn to it from two given points may be equal In what case is this impossible?

SECTION II

PARALLEL STRAIGHT LINES AND PARALLELOGRAMS

DEFINITION Parallel straight lines are such as, being in the same plane, do not meet however far they are produced in both directions

When two straight lines AB , CD are met by a third straight line EF , *eight* angles are formed, to which for the sake of distinction particular names are given

Thus in the adjoining figure,

1, 2, 7, 8 are called exterior angles,

3, 4, 5, 6 are called interior angles,

4 and 6 are said to be alternate angles, so also the angles 3 and 5 are alternate to one another

Of the angles 2 and 6, 2 is referred to as the exterior angle, and 6 as the interior opposite angle on the same side of EF

2 and 6 are sometimes called corresponding angles

So also, 1 and 5, 7 and 3, 8 and 4 are corresponding angles

Euclid's treatment of parallel straight lines is based upon his twelfth Axiom, which we here repeat

AXIOM 12 If a straight line cut two straight lines so as to make the two interior angles on the same side of it together less than two right angles, these straight lines, being continually produced, will at length meet on that side on which are the angles which are together less than two right angles

Thus in the figure given above, if the two angles 3 and 6 are together less than two right angles, it is asserted that AB and CD will meet towards B and D

This Axiom is used to establish 1 29 some remarks upon it will be found in a note on that Proposition

PROPOSITION 27 THEOREM

If a straight line, falling on two other straight lines, make the alternate angles equal to one another, then the straight lines shall be parallel

Let the straight line EF cut the two straight lines AB, CD at G and H, so as to make the alternate angles AGH, GHD equal to one another.

then shall AB and CD be parallel

Proof For if AB and CD be not parallel, they will meet, if produced, either towards B and D, or towards A and C

If possible, let AB and CD, when produced, meet towards B and D, at the point K

Then KGH is a triangle, of which one side KG is produced to A:

therefore the exterior angle AGH is greater than the interior opposite angle GHK

I 16

But the angle AGH is equal to the angle GHK *Hyp*
hence the angles AGH and GHK are both equal and unequal,
which is impossible

Therefore AB and CD cannot meet when produced towards B and D

Similarly it may be shewn that they cannot meet towards A and C

therefore they are parallel.

Q E D.

PROPOSITION 28 THEOREM

If a straight line, falling on two other straight lines, make an exterior angle equal to the interior opposite angle on the same side of the line, or if it make the interior angles on the same side together equal to two right angles, then the two straight lines shall be parallel

Let the straight line EF cut the two straight lines AB, CD in G and H and

First, let the exterior angle EGB be equal to the interior opposite angle GHD

then shall AB and CD be parallel

Proof Because the angle EGB is equal to the angle GHD, and because the angle EGB is also equal to the vertically opposite angle AGH, I 15

therefore the angle AGH is equal to the angle GHD,

but these are alternate angles,

therefore AB and CD are parallel I 27

Q E D

Secondly, let the two interior angles BGH, GHD be together equal to two right angles

then shall AB and CD be parallel

Proof Because the angles BGH, GHD are together equal to two right angles, *Hyp*

and because the adjacent angles BGH, AGH are also together equal to two right angles, I 13

therefore the angles BGH, AGH are together equal to the two angles BGH, GHD

From these equals take the common angle BGH

then the remaining angle AGH is equal to the remaining angle GHD and these are alternate angles,

therefore AB and CD are parallel I 27

Q E D

PROPOSITION 29 THEOREM

If a straight line fall on two parallel straight lines, then it shall make the alternate angles equal to one another, and the exterior angle equal to the interior opposite angle on the same side, and also the two interior angles on the same side equal to two right angles

Let the straight line EF fall on the parallel straight lines AB, CD

- then (i) the alternate angles AGH, GHD shall be equal to one another,
 (ii) the exterior angle EGB shall be equal to the interior opposite angle GHD,
 (iii) the two interior angles BGH, GHD shall be together equal to two right angles

Proof (i) For if the angle AGH be not equal to the angle GHD, one of them must be greater than the other
 If possible, let the angle AGH be greater than the angle GHD,

add to each the angle BGH

then the angles AGH, BGH are together greater than the angles BGH, GHD.

But the adjacent angles AGH, BGH are together equal to two right angles, 13

therefore the angles BGH, GHD are together less than two right angles, 12

therefore AB and CD meet towards B and D *Ax* 12

But they never meet, since they are parallel *Hyp*

Therefore the angle AGH is not unequal to the angle GHD.

that is, the alternate angles AGH, GHD are equal

(Over)

- (ii) Again, because the angle AGH is equal to the vertically opposite angle EGB, I 15
and because the angle AGH is equal to the angle GHD, *Proved*

therefore the exterior angle EGB is equal to the interior opposite angle GHD

- (iii) Lastly, the angle EGB is equal to the angle GHD, *Proved*

add to each the angle BGH,
then the angles EGB, BGH are together equal to the angles BGH, GHD

But the adjacent angles EGB, BGH are together equal to two right angles I. 13

therefore also the two interior angles BGH, GHD are together equal to two right angles Q E D

EXERCISES ON PROPOSITIONS 27, 28, 29

1 Two straight lines AB, CD bisect one another at O shew that the straight lines joining AC and BD are parallel. [I 27]

2 Straight lines which are perpendicular to the same straight line are parallel to one another. [I 27 or I 28]

3. If a straight line meet two or more parallel straight lines, and is perpendicular to one of them, it is also perpendicular to all the others [I 29]

4 If two straight lines are parallel to two other straight lines, each to each, then the angles contained by the first pair are equal respectively to the angles contained by the second pair. [I 29]

NOTE ON THE TWELFTH AXIOM

It must be admitted that Euclid's twelfth Axiom is unsatisfactory as the basis of a theory of parallel straight lines. It cannot be regarded as either simple or self-evident, and it therefore falls short of the essential characteristics of an axiom, nor is the difficulty entirely removed by considering it as a corollary to Proposition 17, of which it is the converse.

Many substitutes have been proposed, but we need only notice here the system which has met with most general approval.

This system rests on the following hypothesis, which is put forward as a fundamental Axiom.

AXIOM. *Two intersecting straight lines cannot be both parallel to a third straight line.*

This statement is known as **Playfair's Axiom**; and though it is not altogether free from objection, it is recommended as both simpler and more fundamental than that employed by Euclid, and more readily admitted without proof.

Propositions 27 and 28 having been proved in the usual way, the first part of Proposition 29 is then given thus.

§ PROPOSITION 29. [ALTERNATIVE PROOF]

If a straight line fall on two parallel straight lines, then it shall make the alternate angles equal.

Let the straight line EF meet the two parallel straight lines AB, CD, at G and H.

then shall the alternate angles AGH, GHD be equal.

For if the angle AGH is not equal to the angle GHD

at G in the straight line HG make the angle HGP equal to the angle GHD, and alternate to it

Then PG and CD are parallel. I. 27.

But AB and CD are parallel. *Hyp.*

therefore the two intersecting straight lines AG, PG are both parallel to CD

which is impossible.

Playfair's Axiom.

Therefore the angle AGH is not unequal to the angle GHD, that is, the alternate angles AGH, GHD are equal. Q. E. D.

The second and third parts of the Proposition may then be deduced as in the text, and Euclid's Axiom 12 follows as a Corollary.

PROPOSITION 30 THEOREM

Straight lines which are parallel to the same straight line are parallel to one another

Let the straight lines AB, CD be each parallel to the straight line PQ

then shall AB and CD be parallel to one another

Construction Draw any straight line EF cutting AB, CD, and PQ in the points G, H, and K

Proof Then because AB and PQ are parallel, and EF meets them,

therefore the angle AGK is equal to the alternate angle GKQ
I 29

And because CD and PQ are parallel, and EF meets them, therefore the exterior angle GHD is equal to the interior opposite angle HKQ
I 29

Therefore the angle AGH is equal to the angle GHD,
and these are alternate angles,

therefore AB and CD are parallel.
I 27

Q.E.D.

NOTE If PQ lies between AB and CD, the Proposition may be established in a similar manner, though in this case it scarcely needs proof, for it is inconceivable that two straight lines, which do not meet an intermediate straight line, should meet one another

The truth of this Proposition may be readily deduced from Playfair's Axiom, of which it is the converse

For if AB and CD were not parallel, they would meet when produced. Then there would be two intersecting straight lines both parallel to a third straight line which is impossible

Therefore AB and CD never meet, that is, they are parallel

PROPOSITION 31 PROBLEM

To draw a straight line through a given point parallel to a given straight line

Let A be the given point, and BC the given straight line. It is required to draw through A a straight line parallel to BC

Construction. In BC take any point D; and join AD. At the point A in DA, make the angle DAE equal to the angle ADC, and alternate to it. I. 23

and produce EA to F.

Then shall EF be parallel to BC

Proof. Because the straight line AD, meeting the two straight lines EF, BC, makes the alternate angles EAD, ADC equal; *Constr*

therefore EF is parallel to BC, I. 27

and it has been drawn through the given point A.

Q. E. D.

EXERCISES

1. Any straight line drawn parallel to the base of an isosceles triangle makes equal angles with the sides

2. If from any point in the bisector of an angle a straight line is drawn parallel to either arm of the angle, the triangle thus formed is isosceles

3. From a given point draw a straight line that shall make with a given straight line an angle equal to a given angle.

4. From X, a point in the base BC of an isosceles triangle ABC, a straight line is drawn at right angles to the base, cutting AB in Y, and CA produced in Z: shew the triangle AYZ is isosceles.

5. If the straight line which bisects an exterior angle of a triangle is parallel to the base, shew that the triangle is isosceles.

PROPOSITION 32 THEOREM

If a side of a triangle be produced, then the exterior angle shall be equal to the sum of the two interior opposite angles also the three interior angles of a triangle are together equal to two right angles

Let ABC be a triangle, and let one of its sides BC be produced to D

- then (i) the exterior angle ACD shall be equal to the sum of the two interior opposite angles CAB, ABC,
 (ii) the three interior angles ABC, BCA, CAB shall be together equal to two right angles

Construction Through C draw CE parallel to BA I 31

Proof. (i) Then because BA and CE are parallel, and AC meets them,

therefore the angle ACE is equal to the alternate angle CAB I 29

Again, because BA and CE are parallel, and BD meets them, therefore the exterior angle ECD is equal to the interior opposite angle ABC I 29

Therefore the whole exterior angle ACD is equal to the sum of the two interior opposite angles CAB, ABC

(ii) Again, since the angle ACD is equal to the sum of the angles CAB, ABC, *Proved*

to each of these equals add the angle BCA
 then the angles BCA, ACD are together equal to the three angles BCA, CAB, ABC.

But the adjacent angles BCA, ACD are together equal to two right angles, I 13

therefore also the angles BCA, CAB, ABC are together equal to two right angles. Q E D

From this Proposition we draw the following important inferences.

1. *If two triangles have two angles of the one equal to two angles of the other, each to each, then the third angle of the one is equal to the third angle of the other*

2. *In any right-angled triangle the two acute angles are complementary.*

3. *In a right-angled isosceles triangle each of the equal angles is half a right angle.*

4. *If one angle of a triangle is equal to the sum of the other two, the triangle is right-angled.*

5. *The sum of the angles of any quadrilateral figure is equal to four right angles.*

6. *Each angle of an equilateral triangle is two-thirds of a right angle.*

EXERCISES ON PROPOSITION 32

1. Prove that the three angles of a triangle are together equal to two right angles,

(i) by drawing through the vertex a straight line parallel to the base;

(ii) by joining the vertex to any point in the base.

2. If the base of any triangle is produced both ways, shew that the sum of the two exterior angles diminished by the vertical angle is equal to two right angles

3. If two straight lines are perpendicular to two other straight lines, each to each, the acute angle between the first pair is equal to the acute angle between the second pair.

4. Every right-angled triangle is divided into two isosceles triangles by a straight line drawn from the right angle to the middle point of the hypotenuse.

Hence the joining line is equal to half the hypotenuse

5. Draw a straight line at right angles to a given finite straight line from one of its extremities, without producing the given straight line.

[Let AB be the given straight line. On AB describe any isosceles triangle ACB. Produce BC to D, making CD equal to BC. Join AD. Then shall AD be perpendicular to AB]

6 *Trisect a right angle*

7 The angle contained by the bisectors of the angles at the base of an isosceles triangle is equal to an exterior angle formed by producing the base

8 The angle contained by the bisectors of two adjacent angles of a quadrilateral is equal to half the sum of the remaining angles

The following theorems were added as corollaries to Proposition 32 by Robert Simson

COROLLARY 1 *All the interior angles of any rectilineal figure, with four right angles, are together equal to twice as many right angles as the figure has sides*

Let ABCDE be any rectilineal figure

Take F, any point within it,

and join F to each of the angular points of the figure

Then the figure is divided into as many triangles as it has sides

And the three angles of each triangle are together equal to two right angles I 32.

Hence all the angles of all the triangles are together equal to twice as many right angles as the figure has sides

But all the angles of all the triangles make up the interior angles of the figure, together with the angles at F,

and the angles at F are together equal to four right angles I 15, Cor

Therefore all the interior angles of the figure, with four right angles, are together equal to twice as many right angles as the figure has sides Q E D

§ COROLLARY 2 *If the sides of a rectilineal figure, which has no re-entrant angle, are produced in order, then all the exterior angles so formed are together equal to four right angles*

For at each angular point of the figure, the interior angle and the exterior angle are together equal to two right angles I. 13

Therefore all the interior angles, with all the exterior angles, are together equal to twice as many right angles as the figure has sides

But all the interior angles, with four right angles, are together equal to twice as many right angles as the figure has sides I. 32, Cor. 1.

Therefore all the interior angles, with all the exterior angles, are together equal to all the interior angles, with four right angles

Therefore the exterior angles are together equal to four right angles. Q E D

EXERCISES ON SIMSON'S COROLLARIES

[A polygon is said to be regular when it has all its sides and all its angles equal]

1 Express in terms of a right angle the magnitude of each angle of (i) a regular hexagon, (ii) a regular octagon

2 If one side of a regular hexagon is produced, shew that the exterior angle is equal to the angle of an equilateral triangle

3 Prove Simson's first Corollary by joining one vertex of the rectilineal figure to each of the other vertices.

4 Find the magnitude of each angle of a regular polygon of n sides

5 If the alternate sides of any polygon be produced to meet, the sum of the included angles, together with eight right angles, will be equal to twice as many right angles as the figure has sides

PROPOSITION 33 THEOREM

The straight lines which join the extremities of two equal and parallel straight lines towards the same parts are themselves equal and parallel

Let AB and CD be equal and parallel straight lines, and let them be joined towards the same parts by the straight lines AC and BD

then shall AC and BD be equal and parallel

Construction

Join BC

Proof Then because AB and CD are parallel, and BC meets them,

therefore the alternate angles ABC, BCD are equal I 29

Now in the triangles ABC, DCB,

Because { AB is equal to DC, *Hyp*
and BC is common to both,
also the angle ABC is equal to the angle DCB, *Proved*

therefore the triangles are equal in all respects, I 4

so that the base AC is equal to the base DB,

and the angle ACB equal to the angle DBC,

but these are alternate angles,

therefore AC and BD are parallel I 27

and it has been shewn that they are also equal

Q E D.

DEFINITION A Parallelogram is a four-sided figure whose opposite sides are parallel

PROPOSITION 34. THEOREM

The opposite sides and angles of a parallelogram are equal to one another, and each diagonal bisects the parallelogram

Let ACDB be a parallelogram, of which BC is a diagonal then shall the opposite sides and angles of the figure be equal to one another, and the diagonal BC shall bisect it

Proof Because AB and CD are parallel, and BC meets them,

therefore the alternate angles ABC, DCB are equal I. 29

Again, because AC and BD are parallel, and BC meets them,

therefore the alternate angles ACB, DBC are equal I. 29

Hence in the triangles ABC, DCB,

Because { the angle ABC is equal to the angle DCB,
and the angle ACB is equal to the angle DBC;
also the side BC, which is adjacent to the equal
angles, is common to both,

therefore the two triangles ABC, DCB are equal in all respects, I. 26

so that AB is equal to DC, and AC to DB;

and the angle BAC is equal to the angle CDB

Also, because the angle ABC is equal to the angle DCB,

and the angle CBD equal to the angle BCA,

therefore the whole angle ABD is equal to the whole angle DCA

And since it has been shewn that the triangles ABC, DCB are equal in all respects,

therefore the diagonal BC bisects the parallelogram ACDB.

Q E D.

[See note on next page]

NOTE To the proof which is here given Euclid added an application of Proposition 4, with a view to shewing that the triangles ABC , DCB are equal in area, and that therefore the diagonal BC bisects the parallelogram. This equality of area is however sufficiently established by the step which depends upon 1 26 [See page 18]

EXERCISES

- 1 If one angle of a parallelogram is a right angle, all its angles are right angles
- 2 If the opposite sides of a quadrilateral are equal, the figure is a parallelogram
- 3 If the opposite angles of a quadrilateral are equal, the figure is a parallelogram
- 4 If a quadrilateral has all its sides equal and one angle a right angle, all its angles are right angles, that is, all the angles of a square are right angles
- 5 The diagonals of a parallelogram bisect each other
- 6 If the diagonals of a quadrilateral bisect each other, the figure is a parallelogram
- 7 If two opposite angles of a parallelogram are bisected by the diagonal which joins them, the figure is equilateral.
- 8 If the diagonals of a parallelogram are equal, all its angles are right angles
- 9 In a parallelogram which is not rectangular the diagonals are unequal
- 10 Any straight line drawn through the middle point of a diagonal of a parallelogram and terminated by a pair of opposite sides, is bisected at that point
- 11 If two parallelograms have two adjacent sides of one equal to two adjacent sides of the other, each to each, and one angle of one equal to one angle of the other, the parallelograms are equal in all respects
- 12 Two rectangles are equal if two adjacent sides of one are equal to two adjacent sides of the other, each to each
- 13 In a parallelogram the perpendiculars drawn from one pair of opposite angles to the diagonal which joins the other pair are equal
- 14 If $ABCD$ is a parallelogram, and X , Y respectively the middle points of the sides AD , BC , shew that the figure $AYCX$ is a parallelogram

MISCELLANEOUS EXERCISES ON SECTIONS I. AND II

1 Shew that the construction in Proposition 2 may generally be performed in eight different ways Point out the exceptional case

2 The bisectors of two vertically opposite angles are in the same straight line

3 In the figure of Proposition 16, if AF is joined, shew

(i) that AF is equal to BC,

(ii) that the triangle ABC is equal to the triangle CFA in all respects.

4 ABC is a triangle right angled at B, and BC is produced to D shew that the angle ACD is obtuse

5 Shew that in any regular polygon of n sides each angle contains $\frac{2(n-2)}{n}$ right angles

6 The angle contained by the bisectors of the angles at the base of any triangle is equal to the vertical angle together with half the sum of the base angles

7. The angle contained by the bisectors of two exterior angles of any triangle is equal to half the sum of the two corresponding interior angles

8 If perpendiculars are drawn to two intersecting straight lines from any point between them, shew that the bisector of the angle between the perpendiculars is parallel to (or coincident with) the bisector of the angle between the given straight lines

9 If two points P, Q be taken in the equal sides of an isosceles triangle ABC, so that BP is equal to CQ, shew that PQ is parallel to BC.

10 ABC and DEF are two triangles, such that AB, BC are equal and parallel to DE, EF, each to each, shew that AC is equal and parallel to DF.

11 Prove the second Corollary to Prop 32 by drawing through any angular point lines parallel to all the sides

12 If two sides of a quadrilateral are parallel, and the remaining two sides equal but not parallel, shew that the opposite angles are supplementary, also that the diagonals are equal.

SECTION III

THE AREAS OF PARALLELOGRAMS AND TRIANGLES

Hitherto when two figures have been said to be *equal*, it has been implied that they are *identically* equal, that is, equal in all respects

In Section III of Euclid's first Book, we have to consider the equality in *area* of parallelograms and triangles which are not necessarily equal in all respects

[The ultimate test of equality, as we have already seen, is afforded by Axiom 8, which asserts that magnitudes which *may be made to coincide with one another* are equal. Now figures which are not identically equal, cannot be made to coincide without first undergoing some change of form: hence the method of direct *superposition* is unsuited to the purposes of the present section.

We shall see however from Euclid's proof of Proposition 35, that two figures which are not identically equal, may nevertheless be so related to a third figure, that it is possible to infer the equality of their areas.]

DEFINITIONS

1 The **Altitude** of a parallelogram with reference to a given side as base, is the perpendicular distance between the base and the opposite side

2 The **Altitude** of a triangle with reference to a given side as base, is the perpendicular distance of the opposite vertex from the base

PROPOSITION 35 THEOREM

Parallelograms on the same base, and between the same parallels, are equal in area

Let the parallelograms ABCD, EBCF be on the same base BC, and between the same parallels BC, AF

then shall the parallelogram ABCD be equal in area to the parallelogram EBCF.

CASE I If the sides of the given parallelograms, opposite to the common base BC, are terminated at the same point D:

then because each of the parallelograms is double of the triangle BDC, I. 34

therefore they are equal to one another Ax 6

CASE II But if the sides AD, EF, opposite to the base BC, are not terminated at the same point

then because ABCD is a parallelogram,

therefore AD is equal to the opposite side BC, I. 34

and for a similar reason, EF is equal to BC,

therefore AD is equal to EF Ax 1

Hence the whole, or remainder, EA is equal to the whole, or remainder, FD

Then in the triangles FDC, EAB,

Because { FD is equal to EA, Proved
and DC is equal to the opposite side AB, I. 34
also the exterior angle FDC is equal to the interior
opposite angle EAB, I. 29

therefore the triangle FDC is equal to the triangle EAB I. 4.

From the whole figure ABCF take the triangle FDC, and from the same figure take the equal triangle EAB,

then the remainders are equal; Ax 3

that is, the parallelogram ABCD is equal to the parallelogram EBCF. Q.E.D.

PROPOSITION 36 THEOREM.

Parallelograms on equal bases, and between the same parallels, are equal in area

Let ABCD, EFGH be parallelograms on equal bases BC, FG, and between the same parallels AH, BG then shall the parallelogram ABCD be equal to the parallelogram EFGH

Construction Join BE, CH

Proof Then because BC is equal to FG, *Hyp*
and FG is equal to the opposite side EH, 1 34
therefore BC is equal to EH *Ax. 1*

and they are also parallel, *Hyp*
therefore BE and CH, which join them towards the same parts, are also equal and parallel 1 33

Therefore EBCH is a parallelogram *Def 26*

Now the parallelogram ABCD is equal to EBCH, for they are on the same base BC, and between the same parallels BC, AH 1 35

Also the parallelogram EFGH is equal to EBCH, for they are on the same base EH, and between the same parallels EH, BG 1 35

Therefore the parallelogram ABCD is equal to the parallelogram EFGH *Ax 1*

Q E D

From the last two Propositions we infer that

- (1) *A parallelogram is equal in area to a rectangle of equal base and equal altitude*
- (2) *Parallelograms on equal bases and of equal altitudes are equal in area*

- (iii) Of two parallelograms of equal altitudes, that is the greater which has the greater base; and of two parallelograms on equal bases, that is the greater which has the greater altitude

PROPOSITION 37 THEOREM

Triangles on the same base, and between the same parallels, are equal in area

Let the triangles ABC, DBC be upon the same base BC, and between the same parallels BC, AD

Then shall the triangle ABC be equal to the triangle DBC.

Construction Through B draw BE parallel to CA, to meet DA produced in E, I 31

through C draw CF parallel to BD, to meet AD produced in F

Proof. Then, by construction, each of the figures EBCA, DBCF is a parallelogram Def. 26

And EBCA is equal to DBCF;

for they are on the same base BC, and between the same parallels BC, EF I 35

And the triangle ABC is half of the parallelogram EBCA, for the diagonal AB bisects it. I 34

Also the triangle DBC is half of the parallelogram DBCF, for the diagonal DC bisects it. I 34

But the halves of equal things are equal, *Ax 7.* therefore the triangle ABC is equal to the triangle DBC

Q.E.D.

PROPOSITION 38 THEOREM

Triangles on equal bases, and between the same parallels, are equal in area

Let the triangles ABC, DEF be on equal bases BC, EF, and between the same parallels BF, AD

then shall the triangle ABC be equal to the triangle DEF

Construction Through B draw BG parallel to CA, to meet DA produced in G, I 31

through F draw FH parallel to ED, to meet AD produced in H

Proof Then, by construction, each of the figures GBCA, DEFH is a parallelogram Def 26

And GBCA is equal to DEFH,

for they are on equal bases BC, EF, and between the same parallels BF, GH I 36

And the triangle ABC is half of the parallelogram GBCA, for the diagonal AB bisects it I 34

Also the triangle DEF is half the parallelogram DEFH, for the diagonal DF bisects it I 34

But the halves of equal things are equal Ax 7 therefore the triangle ABC is equal to the triangle DEF

Q E D

From this Proposition we infer that

(i) *Triangles on equal bases and of equal altitude are equal in area*

(ii) *Of two triangles of the same altitude, that is the greater which has the greater base and of two triangles on the same base, or on equal bases, that is the greater which has the greater altitude*

[For Exercises see page 73]

PROPOSITION 39. THEOREM.

Equal triangles on the same base, and on the same side of it, are between the same parallels

Let the triangles ABC, DBC which stand on the same base BC, and on the same side of it, be equal in area
 then shall they be between the same parallels ;
 that is, if AD be joined, AD shall be parallel to BC

Construction For if AD be not parallel to BC,
 if possible, through A draw AE parallel to BC, I 31
 meeting BD, or BD produced, in E
 Join EC

Proof. Now the triangle ABC is equal to the triangle EBC,
 for they are on the same base BC, and between the same
 parallels BC, AE I 37.

But the triangle ABC is equal to the triangle DBC, *Hyp*
 therefore also the triangle DBC is equal to the triangle EBC,
 the whole equal to the part, which is impossible

Therefore AE is not parallel to BC.

Similarly it can be shewn that no other straight line
 through A, except AD, is parallel to BC

Therefore AD is parallel to BC

Q E D

From this Proposition it follows that.

Equal triangles on the same base have equal altitudes.

[For Exercises see page 73]

PROPOSITION 40 THEOREM

Equal triangles, on equal bases in the same straight line, and on the same side of it, are between the same parallels

Let the triangles ABC , DEF which stand on equal bases BC , EF , in the same straight line BF , and on the same side of it, be equal in area

then shall they be between the same parallels,
that is, if AD be joined, AD shall be parallel to BF

Construction For if AD be not parallel to BF ,
if possible, through A draw AG parallel to BF , 1 31
meeting ED , or ED produced, in G
Join GF

Proof Now the triangle ABC is equal to the triangle GEF ,
for they are on equal bases BC , EF , and between the
same parallels BF , AG 1 38

But the triangle ABC is equal to the triangle DEF *Hyp*
therefore also the triangle DEF is equal to the triangle GEF
the whole equal to the part, which is impossible

Therefore AG is not parallel to BF

Similarly it can be shewn that no other straight line
through A , except AD , is parallel to BF

Therefore AD is parallel to BF

Q E D

From this Proposition it follows that

- (i) *Equal triangles on equal bases have equal altitudes*
- (ii) *Equal triangles of equal altitudes have equal bases*

EXERCISES ON PROPOSITIONS 37—40

DEFINITION Each of the three straight lines which join the angular points of a triangle to the middle points of the opposite sides is called a **Median** of the triangle

ON PROP 37

- 1 If, in the figure of Prop 37, AC and BD intersect in K, shew that
 - (i) the triangles AKB, DKC are equal in area
 - (ii) the quadrilaterals EBKA, FCKD are equal
- 2 In the figure of 1 16, shew that the triangles ABC, FBC are equal in area.
- 3 On the base of a given triangle construct a second triangle, equal in area to the first, and having its vertex in a given straight line
4. Describe an isosceles triangle equal in area to a given triangle and standing on the same base

ON PROP 38

5. *A triangle is divided by each of its medians into two parts of equal area*
- 6 A parallelogram is divided by its diagonals into four triangles of equal area
- 7 ABC is a triangle, and its base BC is bisected at X, if Y be any point in the median AX, shew that the triangles ABY, ACY are equal in area
- 8 In AC, a diagonal of the parallelogram ABCD, any point X is taken, and XB, XD are drawn shew that the triangle BAX is equal to the triangle DAX
- 9 If two triangles have two sides of one respectively equal to two sides of the other, and the angles contained by those sides *supplementary*, the triangles are equal in area

ON PROP 39.

- 10 *The straight line which joins the middle points of two sides of a triangle is parallel to the third side*
- 11 If two straight lines AB, CD intersect in O, so that the triangle AOC is equal to the triangle DOB, shew that AD and CB are parallel

ON PROP 40.

- 12 Deduce Prop 40 from Prop 39 by joining AE, AF in the figure of page 72

PROPOSITION 41 THEOREM

If a parallelogram and a triangle be on the same base and between the same parallels, the parallelogram shall be double of the triangle

Let the parallelogram ABCD, and the triangle EBC be upon the same base BC, and between the same parallels BC, AE
then shall the parallelogram ABCD be double of the triangle EBC

Construction

Join AC

Proof Then the triangle ABC is equal to the triangle EBC, for they are on the same base BC, and between the same parallels BC, AE

I 37

But the parallelogram ABCD is double of the triangle ABC, for the diagonal AC bisects the parallelogram

I 34

Therefore the parallelogram ABCD is also double of the triangle EBC

Q E D

EXERCISES

1 ABCD is a parallelogram, and X, Y are the middle points of the sides AD, BC, if Z is any point in XY, or XY produced, shew that the triangle AZB is one quarter of the parallelogram ABCD

2 Describe a right-angled isosceles triangle equal to a given square

3 If ABCD is a parallelogram, and XY any points in DC and AD respectively shew that the triangles AXB, BYC are equal in area

4 ABCD is a parallelogram, and P is any point within it, shew that the sum of the triangles PAB, PCD is equal to half the parallelogram

PROPOSITION 42. PROBLEM

To describe a parallelogram that shall be equal to a given triangle, and have one of its angles equal to a given angle

Let ABC be the given triangle, and D the given angle
It is required to describe a parallelogram equal to ABC, and
having one of its angles equal to D.

Construction Bisect BC at E I 10

At E in CE, make the angle CEF equal to D, I 23

through A draw AFG parallel to EC, I 31

and through C draw CG parallel to EF

Then FECG shall be the parallelogram required

Join AE.

Proof. Now the triangles ABE, AEC are equal,
for they are on equal bases BE, EC, and between the same
parallels; I 38

therefore the triangle ABC is double of the triangle AEC

But FECG is a parallelogram by construction, *Def.* 26

and it is double of the triangle AEC,

for they are on the same base EC, and between the same
parallels EC and AG I 41

Therefore the parallelogram FECG is equal to the triangle
ABC;

and it has one of its angles CEF equal to the given angle D

Q E F

EXERCISES

1 Describe a parallelogram equal to a given square standing on the same base, and having an angle equal to half a right angle

2 Describe a rhombus equal to a given parallelogram and standing on the same base When does the construction fail?

DEFINITION If in the diagonal of a parallelogram any point is taken, and straight lines are drawn through it parallel to the sides of the parallelogram, then of the four parallelograms into which the whole figure is divided, the two through which the diagonal passes are called *Parallelograms about that diagonal*, and the other two, which with these make up the whole figure, are called the *complements of the parallelograms about the diagonal*

Thus in the figure given below, AEKH, KGCF are parallelograms about the diagonal AC, and HKFD, EBGK are the complements of those parallelograms

¶ **NOTE** A parallelogram is often named by *two* letters only, these being placed at opposite angular points

PROPOSITION 43 THEOREM

The complements of the parallelograms about the diagonal of any parallelogram, are equal to one another

Let ABCD be a parallelogram, and KD, KB the complements of the parallelograms EH, GF about the diagonal AC then shall the complement BK be equal to the complement KD

Proof Because EH is a parallelogram, and AK its diagonal, therefore the triangle AEK is equal to the triangle AHK. 1 34 For a similar reason the triangle KGC is equal to the triangle KFC

Hence the triangles AEK, KGC are together equal to the triangles AHK, KFC

But the whole triangle ABC is equal to the whole triangle ADC, for AC bisects the parallelogram ABCD, I 34
therefore the remainder, the complement BK, is equal to the
remainder, the complement KD Q E D

EXERCISES

In the figure of Prop, 43, prove that

- (i) The parallelogram ED is equal to the parallelogram BH
- (ii) If KB, KD are joined, the triangle AKB is equal to the triangle AKD

PROPOSITION 44 PROBLEM

To a given straight line to apply a parallelogram which shall be equal to a given triangle, and have one of its angles equal to a given angle

Let AB be the given straight line, C the given triangle, and D the given angle

It is required to apply to the straight line AB a parallelogram equal to the triangle C, and having an angle equal to the angle D

Construction On AB produced describe a parallelogram BEFG equal to the triangle C, and having the angle EBG equal to the angle D, I 22 and I. 42*.
through A draw AH parallel to BG or EF, to meet FG produced in H I 31

Join HB

* This step of the construction is effected by first describing on AB produced a triangle whose sides are respectively equal to those of the triangle C (I 22), and by then making a parallelogram equal to the triangle so drawn, and having an angle equal to D (I 42)

PROPOSITION 45. PROBLEM.

To describe a parallelogram equal to a given rectilineal figure, and having an angle equal to a given angle

Let ABCD be the given rectilineal figure, and E the given angle

It is required to describe a parallelogram equal to ABCD, and having an angle equal to E.

Suppose the given rectilineal figure to be a quadrilateral

Construction. Join BD

Describe the parallelogram FKH equal to the triangle ABD, and having the angle FKH equal to the angle E I 42.

To GH apply the parallelogram GM, equal to the triangle DBC, and having the angle GHM equal to E I 44

Then shall FKML be the parallelogram required

Proof. Because each of the angles GHM, FKH is equal to E, therefore the angle FKH is equal to the angle GHM

To each of these equals add the angle GHK;
then the angles FKH, GHK are together equal to the angles GHM, GHK

But since FK, GH are parallel, and KH meets them, therefore the angles FKH, GHK are together equal to two right angles: I 29.

therefore also the angles GHM, GHK are together equal to two right angles.

therefore KH, HM are in the same straight line. I. 14.

PROPOSITION 47. THEOREM

In a right-angled triangle the square described on the hypotenuse is equal to the sum of the squares described on the other two sides

Let ABC be a right-angled triangle, having the angle BAC a right angle
then shall the square described on the hypotenuse BC be
equal to the sum of the squares described on BA , AC

Construction On BC describe the square $BDEC$, r 46
and on BA , AC describe the squares $BAGF$, $ACKH$
Through A draw AL parallel to BD or CE , i 31
and join AD , FC

Proof Then because each of the angles BAC , BAG is a
right angle,
therefore CA and AG are in the same straight line r 14

Now the angle CBD is equal to the angle FBA ,
for each of them is a right angle

[All

Add to each the angle ABC :
then the whole angle ABD is equal to the whole angle FBC .

Then in the triangles ABD, FBC,

Because $\left\{ \begin{array}{l} \text{AB is equal to FB,} \\ \text{and BD is equal to BC,} \\ \text{also the angle ABD is equal to the angle FBC;} \end{array} \right.$
therefore the triangle ABD is equal to the triangle FBC. I 4

Now the parallelogram BL is double of the triangle ABD, for they are on the same base BD, and between the same parallels BD, AL. I 41

And the square GB is double of the triangle FBC, for they are on the same base FB, and between the same parallels FB, GC I 41

But doubles of equals are equal Ax 6
therefore the parallelogram BL is equal to the square GB

In a similar way, by joining AE, BK, it can be shewn that the parallelogram CL is equal to the square CH

Therefore the whole square BE is equal to the sum of the squares GB, HC

that is, the square described on the hypotenuse BC is equal to the sum of the squares described on the two sides BA, AC Q.E.D

NOTE It is not necessary to the proof of this Proposition that the three squares should be described *external* to the triangle ABC, and since *each* square may be drawn either *towards* or *away from* the triangle, it may be shewn that there are $2 \times 2 \times 2$, or *eight*, possible constructions

EXERCISES

1 In the figure of this Proposition, shew that

(i) If BG, CH are joined, these straight lines are parallel,

(ii) The points F, A, K are in one straight line,

(iii) FC and AD are at right angles to one another,

(iv) If GH, KE, FD are joined, the triangle GAH is equal to the given triangle in all respects, and the triangles FBD, KCE are each equal in area to the triangle ABC.

[See Ex 9, p 73.]

2 On the sides AB , AC of any triangle ABC , squares $ABFG$, $ACKH$ are described both toward the triangle, or both on the side remote from it shew that the straight lines BH and CG are equal

3 On the sides of any triangle ABC , equilateral triangles BCX , CAY , ABZ are described, all externally, or all towards the triangle shew that AX , BY , CZ are all equal

4 The square described on the diagonal of a given square, is double of the given square

5 ABC is an equilateral triangle, and AX is the perpendicular drawn from A to BC shew that the square on AX is three times the square on BX

6 Describe a square equal to the sum of two given squares

7 From the vertex A of a triangle ABC , AX is drawn perpendicular to the base shew that the difference of the squares on the sides AB and AC , is equal to the difference of the squares on BX and CX , the segments of the base

8 If from any point O within a triangle ABC , perpendiculars OX , OY , OZ are drawn to the sides BC , CA , AB respectively, shew that the sum of the squares on the segments AZ , BX , CY is equal to the sum of the squares on the segments AY , CX , BZ

PROPOSITION 47 ALTERNATIVE PROOF

Let CAB be a right-angled triangle, having the angle at A a right angle
then shall the square on the hypotenuse BC be equal to the sum of the squares on BA , AC

On AB describe the square ABFG. 1 16.
 From FG and GA cut off respectively FD and GK, each equal
 to AC. 1. 8

On GK describe the square GKEH 1 16
 then HG and GF are in the same straight line. 1 11.
 Join CE, ED, DB

It will first be shewn that the figure CEDB is the square on CB

Now CA is equal to KG, add to each AK
 therefore CK is equal to AG
 Similarly DH is equal to GF
 hence the four lines BA, CK, DH, BF are all equal.

Then in the triangles BAC, CKE,

Because { BA is equal to CK *Proved.*
 { and AC is equal to KE, *Constr.*
 { also the contained angle BAC is equal to the contained
 angle CKE, being right angles;
 therefore the triangles BAC, CKE are equal in all respects. 1. 1.
 Similarly the four triangles BAC, CKE, DHE, BFD may be shewn
 to be equal in all respects.

Therefore the four straight lines BC, CE, ED, DB are all equal,
 that is, the figure CEDB is equilateral

Again the angle CBA is equal to the angle DBF; *Proved*
 add to each the angle ABD

then the angle CBD is equal to the angle ABF.

therefore the angle CBD is a right angle

Hence the figure CEDB is the square on BC *Def 28*

And EHGK is equal to the square on AC. *Constr.*

Now the square on CEDB is made up of the two triangles BAC, CKE,
 and the rectilineal figure AKEDB,

therefore the square CEDB is equal to the triangles EHD, DFB
 together with the same rectilineal figure,

but these make up the squares EHGK, AGFB:

hence the square CEDB is equal to the sum of the squares EHGK,
 AGFB:

that is, the square on the hypotenuse BC is equal to the sum of the
 squares on the two sides CA, AB. *Q. E. D.*

Obs The following properties of a square, though not
 formally enunciated by Euclid, are employed in subsequent
 proofs [See 1 18]

(i) *The squares on equal straight lines are equal*

(ii) *Equal squares stand upon equal straight lines*

PROPOSITION 48 THEOREM

If the square described on one side of a triangle be equal to the sum of the squares described on the other two sides, then the angle contained by these two sides shall be a right angle

Let ABC be a triangle, and let the square described on BC be equal to the sum of the squares described on BA, AC
then shall the angle BAC be a right angle

Construction From A draw AD at right angles to AC, I 11
and make AD equal to AB I 3
Join DC

Proof Then, because AD is equal to AB, *Constr*
therefore the square on AD is equal to the square on AB

To each of these add the square on CA,
then the sum of the squares on CA, AD is equal to the sum
of the squares on CA, AB

But, because the angle DAC is a right angle, *Constr*
therefore the square on DC is equal to the sum of the
squares on CA, AD I 47

And, by hypothesis, the square on BC is equal to the sum
of the squares on CA, AB,

therefore the square on DC is equal to the square on BC

therefore also the side DC is equal to the side BC

Then in the triangles DAC, BAC,

Because { DA is equal to BA, *Constr*
and AC is common to both,
also the third side DC is equal to the third side
BC, *Proved*

therefore the angle DAC is equal to the angle BAC I 8

But DAC is a right angle, *Constr*
therefore also BAC is a right angle Q E D

THEOREMS AND EXAMPLES ON BOOK I.

INTRODUCTORY.

HINTS TOWARDS THE SOLUTION OF GEOMETRICAL EXERCISES. ANALYSIS. SYNTHESIS.

It is commonly found that exercises in Pure Geometry present to a beginner far more difficulty than examples in any other branch of Elementary Mathematics. This seems to be due to the following causes.

(i) The main Propositions in the text of Euclid must be not merely understood, but thoroughly digested, before the exercises depending upon them can be successfully attempted.

(ii) The variety of such exercises is practically unlimited, and it is impossible to lay down for their treatment any definite methods, such as the student has been accustomed to find in the rules of Elementary Arithmetic and Algebra.

(iii) The arrangement of Euclid's Propositions, though perhaps the most *convincing* of all forms of argument, affords in most cases little clue as to the way in which the proof or construction *was discovered*.

Euclid's propositions are arranged *synthetically*. that is to say, they start from the hypothesis or data, they next proceed to a construction in accordance with postulates, and problems already solved, then by successive steps based on known theorems, they finally establish the result indicated by the enunciation.

Thus Geometrical Synthesis is a *building up* of known results, in order to obtain a *new* result.

But as this is not the way in which constructions or proofs are usually discovered, we draw the attention of the student to the following hints.

Begin by *assuming* the result it is desired to establish; then by working backwards, trace the consequences of the assumption, and try to ascertain its dependence on some simpler theorem which is already known to be true, or on some condition which suggests the necessary construction. If this attempt is successful, the steps of the argument may in general be re-arranged in reverse order, and the construction and proof presented in a synthetic form.

This unravelling of the conditions of a proposition in order to trace it back to some earlier principle on which it depends, is called *geometrical analysis* it is the natural way of attacking most exercises of a more difficult type, and it is especially adapted to the solution of *problems*

These directions are so general that they cannot be said to amount to a *method* all that can be claimed for Geometrical Analysis is that it furnishes a mode of *searching for a suggestion*, and its success will necessarily depend on the skill and *ingenuity* with which it is employed these may be expected to come with experience, but a thorough grasp of the chief Propositions of Euclid is essential to attaining them

The practical application of these hints is illustrated by the following examples

1 Construct an isosceles triangle having given the base, and the sum of one of the equal sides and the perpendicular drawn from the vertex to the base

Let AB be the given base, and K the sum of one side and the perpendicular drawn from the vertex to the base

ANALYSIS Suppose ABC to be the required triangle

From C draw CX perpendicular to AB

then AB is bisected at X

1 26

Now if we produce XC to H, making XH equal to K,

it follows that $CH = CA$,

and if AH is joined,

we notice that the angle $CAH =$ the angle CHA

1 5

Now the straight lines XH and AH can be drawn before the position of C is known,

Hence we have the following construction, which we arrange synthetically

SYNTHESIS From B draw BD perpendicular to AB,
and from A draw AC, making $\angle BAC$ one-fourth of a right angle
From C, the intersection of AC and BD, draw CX, making the angle
 $\angle ACX$ equal to the angle $\angle BAC$ 1 23.

Then AB shall be divided as required at X

For since the angle $\angle XCA = \text{the angle } \angle XAC$,

$$XA = XC$$

And because the angle $\angle BXC = \text{the sum of the angles } \angle BAC, \angle ACX$, 1 6

the angle $\angle BXC$ is half a right angle,

and the angle at B is a right angle,

therefore the angle $\angle BCX$ is half a right angle, 1 32

therefore the angle $\angle BXC = \text{the angle } \angle BCX$,

$$BX = BC$$

Hence the square on XC is double of the square on XB 1 47
that is, the square on AX is double of the square on XB q e f.

I ON THE IDENTICAL EQUALITY OF TRIANGLES

See Propositions 4, 8, 26

1 If in a triangle the perpendicular from the vertex on the base bisects the base, then the triangle is isosceles

2 If the bisector of the vertical angle of a triangle is also perpendicular to the base, the triangle is isosceles

3 If the bisector of the vertical angle of a triangle also bisects the base, the triangle is isosceles

[Produce the bisector, and complete the construction after the manner of 1 16]

4 If in a triangle a pair of straight lines drawn from the extremities of the base, making equal angles with the sides, are equal, the triangle is isosceles

5 If in a triangle the perpendiculars drawn from the extremities of the base to the opposite sides are equal, the triangle is isosceles

6 Two triangles ABC, ABD on the same base AB, and on opposite sides of it, are such that AC is equal to AD, and BC is equal to BD shew that the line joining the points C and D is perpendicular to AB

7 If from the extremities of the base of an isosceles triangle perpendiculars are drawn to the opposite sides, shew that the straight line joining the vertex to the intersection of these perpendiculars bisects the vertical angle

8 ABC is a triangle in which the vertical angle BAC is bisected by the straight line AX from B draw BD perpendicular to AX , and produce it to meet AC , or AC produced, in E , then shew that BD is equal to DE

9 In a quadrilateral $ABCD$, AB is equal to AD , and BC is equal to DC shew that the diagonal AC bisects each of the angles which it joins

10 In a quadrilateral $ABCD$ the opposite sides AD , BC are equal, and also the diagonals AC , BD are equal if AC and BD intersect at K , shew that each of the triangles AKB , DKC is isosceles.

11. If one angle of a triangle be equal to the sum of the other two, the greatest side is double of the distance of its middle point from the opposite angle

12 *Two right-angled triangles which have their hypotenuses equal, and one side of one equal to one side of the other, are identically equal*

Let ABC , DEF be two Δ^s right-angled at B and E , having AC equal to DF , and AB equal to DE

then shall the Δ^s be identically equal

For apply the ΔABC to the ΔDEF , so that A may fall on D , and AB along DE , and so that C may fall on the side of DE remote from F

Let C' be the point on which C falls

Then since $AB=DE$,

B must fall on E ,

so that DEC' represents the ΔABC in its new position

Now each of the \angle^s DEF , DEC' is a rt \angle ,

EF and EC' are in one st line

Hyp
r 14.

Then in the $\Delta C'DF$,

because $DF=DC'$,

the $\angle DFC' = \text{the } \angle DC'F$

r 5

Hence in the two Δ^s DEF , DEC' ,

the $\angle DEF = \text{the } \angle DEC'$, being rt \angle^s ,

Because { and the $\angle DFE = \text{the } \angle DC'E$,
also the side DE is common to both;

Proved

\therefore the Δ^s DEF , DEC' are equal in all respects,
that is, the Δ^s DEF , ABC are equal in all respects

r 26

Q E D

13. If two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise the angles opposite to one pair of equal sides equal, then the angles opposite to the other pair of equal sides are either equal or supplementary, and in the former case the triangles are equal in all respects

Let $\triangle ABC$, $\triangle DEF$ be two \triangle s,
 having the side AB equal to the side DE ,
 the side AC equal to the side DF ,
 also the $\angle ABC$ equal to the $\angle DEF$
 then shall the $\angle ACB$, $\angle DFE$ be either equal or supplementary,
 and in the former case, the \triangle s shall be equal in all respects

Apply the $\triangle ABC$ to the $\triangle DEF$,
 so that A may fall on D , and AB along DE ,
 then because $AB = DE$, *Hyp*
 B will fall on E
 and because the $\angle ABC = \angle DEF$, *Hyp*
 BC will fall along EF
 Then must C fall on F , or in EF , or EF produced

If C falls on F ,
 the \triangle s coincide, and therefore are identically equal,
 so that the $\angle ACB = \angle DFE$

But if C falls in EF , or EF produced, as at C'
 then DEC' represents the $\triangle ABC$ in its new position
 Then because $DF = AC$, *Hyp*
 $DF = DC'$,
 the $\angle DC'F = \angle DFC'$ I 5
 But the $\angle DFC'$, $\angle DFE$ are supplementary, I 13
 the $\angle DC'F$, $\angle DFE$ are supplementary
 that is, the $\angle ACB$, $\angle DFE$ are supplementary Q E D

Three cases of this theorem deserve special attention

It has been proved that if the angles ACB , DFE are not equal, they are supplementary

And we know that of angles which are supplementary and unequal, one must be acute and the other obtuse

COROLLARIES Hence if in addition to the hypothesis of this theorem it is given

- (i) That the angles ACB , DFE , opposite to the two equal sides AB , DE are both acute, both obtuse, or if one of them is a right angle,
it follows that these angles are equal,
and therefore that the triangles are equal in all respects
- (ii) That the two given angles are right angles or obtuse angles, it follows that the angles ACB , DFE must be both acute, and therefore equal, by (i)
so that the triangles are equal in all respects
- (iii) That in each triangle the side opposite the given angle is not less than the other given side, that is, if AC and DF are not less than AB and DE respectively, then the angles ACB , DFE cannot be greater than the angles ABC , DEF , respectively;
therefore the angles ACB , DFE , are both acute,
hence, as above, they are equal,
and the triangles ABC , DEF are equal in all respects

II ON INEQUALITIES

See Propositions 16, 17, 18, 19, 20, 21, 24, 25

1. In a triangle ABC , if AC is not greater than AB , shew that any straight line drawn through the vertex A , and terminated by the base BC , is less than AB

2 ABC is a triangle, and the vertical angle BAC is bisected by a straight line which meets the base BC in X , shew that BA is greater than BX , and CA greater than CX Hence obtain a proof of 1 20

3 The perpendicular is the shortest straight line that can be drawn from a given point to a given straight line, and of others, that which is nearer to the perpendicular is less than the more remote, and two, and only two equal straight lines can be drawn from the given point to the given straight line, one on each side of the perpendicular.

4 The sum of the distances of any point from the three angular points of a triangle is greater than half its perimeter.

5 The sum of the distances of any point within a triangle from its angular points is less than the perimeter of the triangle

6 The perimeter of a quadrilateral is greater than the sum of its diagonals

7 The sum of the diagonals of a quadrilateral is less than the sum of the four straight lines drawn from the angular points to any given point Prove this, and point out the exceptional case

8 In a triangle any two sides are together greater than twice the median which bisects the remaining side [See Def p 73]

[Produce the median, and complete the construction after the manner of i 16]

9 In any triangle the sum of the medians is less than the perimeter

10 In a triangle an angle is acute, obtuse, or a right angle, according as the median drawn from it is greater than, less than, or equal to half the opposite side [See Ex 4, p 59]

11 The diagonals of a rhombus are unequal

12 If the vertical angle of a triangle is contained by unequal sides, and if from the vertex the median and the bisector of the angle are drawn, then the median lies within the angle contained by the bisector and the longer side

Let ABC be a Δ , in which AB is greater than AC , let AX be the median drawn from A , and AP the bisector of the vertical $\angle BAC$

then shall AX lie between AP and AB

Produce AX to K , making XK equal to AX Join KC

Then the $\Delta^s BXA, CXK$ may be shewn to be equal in all respects, i 4

hence $BA = CK$, and the $\angle BAX = \text{the } \angle CKX$

But since BA is greater than AC , If p

$\therefore CK$ is greater than AC ,

the $\angle CAK$ is greater than the $\angle CKA$

that is, the $\angle CAX$ is greater than the $\angle BAX$

the $\angle CAX$ must be more than half the vert $\angle BAC$,

hence AX lies within the angle BAP .

i 18

Q E D

13 If two sides of a triangle are unequal, and if from their point of intersection three straight lines are drawn, namely the bisector of the vertical angle, the median, and the perpendicular to the base, the first is intermediate in position and magnitude to the other two

III ON PARALLELS

See Propositions 27—31

1. If a straight line meets two parallel straight lines, and the two interior angles on the same side are bisected, shew that the bisectors meet at right angles. [I. 29, 1 32]

2. The straight lines drawn from any point in the bisector of an angle parallel to the arms of the angle, and terminated by them, are equal, and the resulting figure is a rhombus.

3. AB and CD are two straight lines intersecting at D, and the adjacent angles so formed are bisected. If through any point X in DC a straight line YXZ be drawn parallel to AB and meeting the bisectors in Y and Z, shew that XY is equal to XZ.

4. If two straight lines are parallel to two other straight lines each to each, and if the angles contained by each pair are bisected, shew that the bisecting lines are parallel.

5. The middle point of any straight line which meets two parallel straight lines, and is terminated by them, is equidistant from the parallels.

6. A straight line drawn between two parallels and terminated by them, is bisected, shew that any other straight line passing through the middle point and terminated by the parallels, is also bisected at that point.

7. If through a point equidistant from two parallel straight lines, two straight lines are drawn cutting the parallels, the portions of the latter thus intercepted are equal.

PROBLEMS

8. AB and CD are two given straight lines, and X is a given point in AB. find a point Y in AB such that YX may be equal to the perpendicular distance of Y from CD.

9. ABC is an isosceles triangle; required to draw a straight line DE parallel to the base BC, and meeting the equal sides in D and E, so that BD, DE, EC may be all equal.

10. ABC is any triangle; required to draw a straight line DE parallel to the base BC, and meeting the other sides in D and E, so that DE may be equal to the sum of BD and CE.

11. ABC is any triangle; required to draw a straight line parallel to the base BC, and meeting the other sides in D and E, so that DE may be equal to the difference of BD and CE.

IV ON PARALLELOGRAMS

See Propositions 33, 34, and the deductions from these Props given on page 64.

1 *The straight line drawn through the middle point of a side of a triangle parallel to the base, bisects the remaining side*

Let ABC be a Δ , and Z the middle point of the side AB . Through Z , ZY is drawn par^1 to BC , then shall Y be the middle point of AC

Through Z draw $ZX \text{ par}^1$ to AC $\text{I } 31$

Then in the $\Delta^s AZY, ZBX$,
because ZY and BC are par^1 ,
the $\angle AZY = \text{the } \angle ZBX$, $\text{I } 29$
and because ZX and AC are par^1 ,
the $\angle ZAY = \text{the } \angle BZX$, $\text{I } 29$
also $AZ = ZB$ *Hyp*

$AY = ZX$

$\text{I } 26$

But $ZXCY$ is a par^m by construction,

$ZX = YC$

$\text{I } 34$

Hence $AY = YC$,

that is, AC is bisected at Y

Q E D

2 *The straight line which joins the middle points of two sides of a triangle, is parallel to the third side*

Let ABC be a Δ , and Z, Y the middle points of the sides AB, AC

then shall ZY be par^1 to BC

Produce ZY to V , making YV equal to ZY

Join CV

Then in the $\Delta^s AYZ, CYV$,

Because { $AY = CY$, *Hyp*
 and $YZ = YV$, *Constr*
 and the $\angle AYZ = \text{the vert opp } \angle CYV$,

$\text{I } 15$

$AZ = CV$,

$\text{I } 4$

and the $\angle ZAY = \text{the } \angle VCY$,

hence CV is par^1 to AZ

$\text{I } 27$

But CV is equal to AZ , that is, to BZ

Hyp

CV is equal and par^1 to BZ

ZV is equal and par^1 to BC

$\text{I } 33$

that is, ZY is par^1 to BC

Q E D

[A second proof of this proposition may be derived from $\text{I } 38, 39$]

3. *The straight line which joins the middle points of two sides of a triangle is equal to half the third side.*

4. *Shew that the three straight lines which join the middle points of the sides of a triangle, divide it into four triangles which are identically equal.*

5. *Any straight line drawn from the vertex of a triangle to the base is bisected by the straight line which joins the middle points of the other sides of the triangle*

6. *Given the three middle points of the sides of a triangle, construct the triangle.*

7. *AB, AC are two given straight lines, and P is a given point between them, required to draw through P a straight line terminated by AB, AC, and bisected by P.*

8. *ABCD is a parallelogram, and X, Y are the middle points of the opposite sides AD, BC shew that BX and DY trisect the diagonal AC.*

9. *If the middle points of adjacent sides of any quadrilateral be joined, the figure thus formed is a parallelogram.*

10. *Shew that the straight lines which join the middle points of opposite sides of a quadrilateral, bisect one another.*

11. *The straight line which joins the middle points of the oblique sides of a trapezium, is parallel to the two parallel sides, and passes through the middle points of the diagonals.*

12. *The straight line which joins the middle points of the oblique sides of a trapezium is equal to half the sum of the parallel sides, and the portion intercepted between the diagonals is equal to half the difference of the parallel sides*

Definition If from the extremities of one straight line perpendiculars are drawn to another, the portion of the latter intercepted between the perpendiculars is said to be the **Orthogonal Projection** of the first line upon the second.

Thus in the adjoining figures, if from the extremities of the straight line AB the perpendiculars AX, BY are drawn to PQ, then XY is the *orthogonal projection* of AB on PQ

13 A given straight line AB is bisected at C, shew that the projections of AC, CB on any other straight line are equal

Let XZ, ZY be the projections of AC, CB on any straight line PQ then XZ and ZY shall be equal

Through A draw a straight line parallel to PQ, meeting CZ, BY or these lines produced, in H, K

Now AX, CZ, BY are parallel, for they are perp to PQ, I 28
the figures XH, HY are paral^{ls},

AH = XZ, and HK = ZY I 34

But through C, the middle point of AB, a side of the $\triangle ABK$, CH has been drawn parallel to the side BK,

CH bisects AK,

that is, AH = HK,

XZ = ZY

Ex 1, p 96

Q E D

14 If three parallel straight lines make equal intercepts on a fourth straight line which meets them, they will also make equal intercepts on any other straight line which meets them

15 Equal and parallel straight lines have equal projections on any other straight line

16 AB is a given straight line bisected at O, and AX, BY are perpendiculars drawn from A and B on any other straight line. shew that OX is equal to OY

17 AB is a given straight line bisected at O and AX, BY and OZ are perpendiculars drawn to any straight line PQ, which does not pass between A and B shew that OZ is equal to half the sum of AX, BY

[OZ is said to be the Arithmetic Mean between AX and BY]

18 AB is a given straight line bisected at O, and through A, B and O parallel straight lines are drawn to meet a given straight line PQ in X, Y, Z shew that OZ is equal to half the sum, or half the difference of AX and BY, according as A and B lie on the same side or on opposite sides of PQ

19 To divide a given finite straight line into any number of equal parts

[For example, required to divide the straight line AB into five equal parts]

From A draw AC, a straight line of unlimited length, making any angle with AB

In AC take any point P, and mark off successive parts PQ, QR, RS, ST each equal to AP

Join BT, and through P, Q, R, S draw parallels to BT

It may be shewn by Ex 14, p 98, that these parallels divide AB into five equal parts]

20 If through an angle of a parallelogram any straight line is drawn, the perpendicular drawn to it from the opposite angle is equal to the sum or difference of the perpendiculars drawn to it from the two remaining angles, according as the given straight line falls without the parallelogram, or intersects it

[Through the opposite angle draw a straight line parallel to the given straight line, so as to meet the perpendicular from one of the remaining angles, produced if necessary then apply I 34, I 26 Or proceed as in the following example]

21 From the angular points of a parallelogram perpendiculars are drawn to any straight line which is without the parallelogram shew that the sum of the perpendiculars drawn from one pair of opposite angles is equal to the sum of those drawn from the other pair

[Draw the diagonals, and from their point of intersection let fall a perpendicular upon the given straight line See Ex 17, p 98]

✓ 22 The sum of the perpendiculars drawn from any point in the base of an isosceles triangle to the equal sides is equal to the perpendicular drawn from either extremity of the base to the opposite side.

[It follows that the sum of the distances of any point in the base of an isosceles triangle from the equal sides is constant, that is, the same whatever point in the base is taken]

23 In the base produced of an isosceles triangle any point is taken shew that the difference of its distances from the equal sides is constant

✓ 24. The sum of the perpendiculars drawn from any point within an equilateral triangle to the three sides is equal to the perpendicular drawn from any one of the angular points to the opposite side, and is therefore constant

PROBLEMS

[Problems marked (*) admit of more than one solution]

*25 Draw a straight line through a given point, so that the part of it intercepted between two given parallel straight lines may be of given length

26 Draw a straight line parallel to a given straight line, so that the part intercepted between two other given straight lines may be of given length

27 Draw a straight line equally inclined to two given straight lines that meet, so that the part intercepted between them may be of given length

28 AB, AC are two given straight lines, and P is a given point *without* the angle contained by them. It is required to draw through P a straight line to meet the given lines, so that the part intercepted between them may be equal to the part between P and the nearer line

V MISCELLANEOUS THEOREMS AND EXAMPLES

Chiefly on I 32

1 A is the vertex of an isosceles triangle ABC, and BA is produced to D, so that AD is equal to BA, if DC is drawn, shew that BCD is a right angle

2 The straight line joining the middle point of the hypotenuse of a right-angled triangle to the right angle is equal to half the hypotenuse

3 From the extremities of the base of a triangle perpendiculars are drawn to the opposite sides (produced if necessary), shew that the straight lines which join the middle point of the base to the feet of the perpendiculars are equal

4 In a triangle ABC, AD is drawn perpendicular to BC, and X, Y, Z are the middle points of the sides BC, CA, AB respectively - shew that each of the angles ZXY, ZDY is equal to the angle BAC

5 In a right-angled triangle, if a perpendicular be drawn from the right angle to the hypotenuse, the two triangles thus formed are equiangular to one another

6 In a right-angled triangle two straight lines are drawn from the right angle, one bisecting the hypotenuse, the other perpendicular to it shew that they contain an angle equal to the difference of the two acute angles of the triangle [See above, Ex 2 and Ex 5]

7 In a triangle if a perpendicular be drawn from one extremity of the base to the bisector of the vertical angle, (i) it will make with either of the sides containing the vertical angle an angle equal to half the sum of the angles at the base, (ii) it will make with the base an angle equal to half the difference of the angles at the base

Let ABC be the given Δ , and AH the bisector of the vertical $\angle BAC$.

Let CK meet AH at right angles

(i) Then shall each of the $\angle^s AKC, ACK$ be equal to half the sum of the $\angle^s ABC, ACB$

In the $\Delta^s AKL, ACL$,
 the $\angle KAL = \text{the } \angle CAL$,
 Because { also the $\angle ALK = \text{the } \angle ALC$, being rt \angle^s ,
 and AL is common to both Δ^s ,
 the $\angle AKL = \text{the } \angle ACL$.

I 26

Again, the $\angle AKC = \text{the sum of the } \angle^s KBC, KCB$,
 that is, the $\angle ACK = \text{the sum of the } \angle^s KBC, KCB$

I 32.

To each add the $\angle ACK$,
 then twice the $\angle ACK = \text{the sum of the } \angle^s ABC, ACB$,
 the $\angle ACK = \text{half the sum of the } \angle^s ABC, ACB$

(ii) The $\angle KCB$ shall be equal to half the difference of the $\angle^s ACB, ABC$

As before, the $\angle ACK = \text{the sum of the } \angle^s KBC, KCB$.

To each of these add the $\angle KCB$

then the $\angle ACB = \text{the } \angle KBC$ together with twice the $\angle KCB$

\therefore twice the $\angle KCB = \text{the difference of the } \angle^s ACB, KBC$,
 that is, the $\angle KCB = \text{half the difference of the } \angle^s ACB, ABC$

COROLLARY If X be the middle point of the base, and XL be joined, it may be shewn by Ex 3, p 97, that XL is half BK , that is, that XL is half the difference of the sides AB, AC .

8 In any triangle the angle contained by the bisector of the vertical angle and the perpendicular from the vertex to the base is equal to half the difference of the angles at the base. [See Ex 3, p 59]

9 In a triangle ABC the side AC is produced to D , and the angles BAC, BCD are bisected by straight lines which meet at F , shew that they contain an angle equal to half the angle at B

10 If in a right-angled triangle one of the acute angles is double of the other, shew that the hypotenuse is double of the shorter side.

11. If in a diagonal of a parallelogram any two points equidistant from its extremities be joined to the opposite angles, the figure thus formed will be also a parallelogram

12 ABC is a given equilateral triangle, and in the sides BC , CA , AB the points X , Y , Z are taken respectively, so that BX , CY and AZ are all equal. AX , BY , CZ are now drawn, intersecting in P , Q , R . shew that the triangle PQR is equilateral.

13 If in the sides AB , BC , CD , DA of a parallelogram $ABCD$ four points P , Q , R , S be taken in order, one in each side, so that AP , BQ , CR , DS are all equal, shew that the figure $PQRS$ is a parallelogram.

14 In the figure of 1.1, if the circles intersect at F , and if CA and CB are produced to meet the circles in P and Q respectively, shew that the points P , F , Q are in the same straight line, and shew also that the triangle CPQ is equilateral.

[Problems marked (*) admit of more than one solution.]

15 Through two given points draw two straight lines forming with a straight line given in position, an equilateral triangle.

*16 From a given point it is required to draw to two parallel straight lines two equal straight lines at right angles to one another.

*17 Three given straight lines meet at a point, draw another straight line so that the two portions of it intercepted between the given lines may be equal to one another.

18 From a given point draw three straight lines of given lengths, so that their extremities may be in the same straight line, and intercept equal distances on that line. [See Fig. to 1.16.]

19 Use the properties of the equilateral triangle to trisect a given finite straight line.

20 In a given triangle inscribe a rhombus, having one of its angles coinciding with an angle of the triangle.

VI ON THE CONCURRENCE OF STRAIGHT LINES IN A TRIANGLE

DEFINITIONS (1) Three or more straight lines are said to be **concurrent** when they meet in one point.

(2) Three or more points are said to be **collinear** when they lie upon one straight line.

We here give some propositions relating to the concurrence of certain groups of straight lines drawn in a triangle. the importance of these theorems will be more fully appreciated when student is familiar with Books III and IV.

Similarly from the Δ^s OCP, OCQ,
it may be shewn that $OP=OQ$,
 OP, OQ, OR are all equal

Again in the Δ^s ORA, OQA,
the \angle^s ORA, OQA are rt \angle^s ,
Because { and the hypotenuse OA is
common,
also $OR=OQ$, Proved
the \angle RAO = the \angle QAO

Ex 12, p 91

That is, AO is the bisector of the \angle BAC

Hence the bisectors of the three \angle^s meet at the point O

Q F D

3 The bisectors of two exterior angles of a triangle and the bisector of the third angle are concurrent

Let ABC be a Δ , of which the sides AB, AC are produced to any points D and E

Bisect the \angle^s DBC, ECB by straight lines
which must meet at some point O Ax 12
Join AO

It is required to prove that AO bisects the angle BAC

From O draw OP, OQ, OR perp to the sides of the Δ

Then in the Δ^s OBP, OBR,
Because { the \angle OBP = the \angle OBR, Constr
also the \angle OPB = the \angle ORB,
being rt \angle^s ,
and OB is common,
 $OP=OR$

I 26

Similarly in the Δ^s OCP, OCQ,
it may be shewn that $OP=OQ$
 OP, OQ, OR are all equal

Again in the Δ^s ORA, OQA,
the \angle^s ORA, OQA are rt \angle^s ,
Because { -and the hypotenuse OA is common,
also $OR=OQ$,
the \angle RAO = the \angle QAO

Proved
Ex 12, p 91

That is, AO is the bisector of the \angle BAC
the bisectors of the two exterior \angle^s DBC, ECB,
and of the interior \angle BAC meet at the point O

Q E D

4 The medians of a triangle are concurrent

Let ABC be a Δ . Let BY and CZ be two of its medians, and let them intersect at O

Join AO ,

and produce it to meet BC in X .

It is required to shew that AX is the remaining median of the Δ

Through C draw CK parallel to BY .

produce AX to meet CK at K

Join BK .

In the ΔAKC ,

because Y is the middle point of AC , and YO is parallel to CK ,

$\therefore O$ is the middle point of AK

Ex. 1, p 96

Again in the ΔABK ,

since Z and O are the middle points of AB , AK ,

$\therefore ZO$ is parallel to BK ,

Ex 2, p. 96

that is, OC is parallel to BK .

\therefore the figure $BKCO$ is a par^m .

But the diagonals of a par^m bisect one another,

Ex 5, p 64

$\therefore X$ is the middle point of BC .

That is, AX is a median of the Δ .

Hence the three medians meet at the point O Q.E.D.

COROLLARY. The three medians of a triangle cut one another at a point of trisection, the greater segment in each being towards the angular point.

For in the above figure it has been proved that

$$AO = OK,$$

also that OX is half of OK ,

$\therefore OX$ is half of OA .

that is, OX is one third of AX

Similarly OY is one third of BY ,

and OZ is one third of CZ

Q.E.D.

By means of this Corollary it may be shewn that in any triangle the shorter median bisects the greater side.

[The point of intersection of the three medians of a triangle is called the centroid. It is shewn in mechanics that a thin triangular plate will balance in any position about this point therefore the centroid of a triangle is also its centre of gravity.]

5 The perpendiculars drawn from the vertices of a triangle to the opposite sides are concurrent

Let ABC be a Δ , and AD , BE , CF the three perp^s drawn from the vertices to the opposite sides
then shall these perp^s be concurrent

Through A , B , and C draw straight lines MN , NL , LM parallel to the opposite sides of the Δ

Then the figure $BAMC$ is a par^m

$$AB = MC$$

Def 26

I 31

Also the figure $BACL$ is a par^m

$$AB = LC,$$

$$LC = CM$$

that is, C is the middle point of LM

So also A and B are the middle points of MN and NL

Hence AD , BE , CF are the perp^s to the sides of the ΔLMN from their middle points

Ex 3, p 54

But these perp^s meet in a point

Ex 1, p 103

that is, the perp^s drawn from the vertices of the ΔABC to the opposite sides meet in a point

Q. E. D.

[For another proof see Theorems and Examples on Book III]

DEFINITIONS

(i) The intersection of the perpendiculars drawn from the vertices of a triangle to the opposite sides is called its **orthocentre**

(ii) The triangle formed by joining the feet of the perpendiculars is called the **pedal triangle**

VII. ON THE CONSTRUCTION OF TRIANGLES WITH GIVEN PARTS

No general rules can be laid down for the solution of problems in this section, but in a few typical cases we give constructions, which the student will find little difficulty in adapting to other questions of the same class

1 Construct a right-angled triangle, having given the hypotenuse and the sum of the remaining sides

[It is required to construct a rt angled Δ , having its hypotenuse equal to the given straight line K , and the sum of its remaining sides equal to AB

From A draw AE making with BA an \angle equal to half a rt \angle . From centre B , with radius equal to K , describe a circle cutting AE in the points C, C'

From C and C' draw perp^s $CD, C'D'$ to AB , and join $CB, C'B$. Then either of the Δ^s $CDB, C'D'B$ will satisfy the given conditions.

NOTE If the given hypotenuse K be greater than the perpendicular drawn from B to AE , there will be *two* solutions. If the line K be equal to this perpendicular, there will be *one* solution, but if less, the problem is *impossible*]

2 Construct a right-angled triangle, having given the hypotenuse and the difference of the remaining sides

3 Construct an isosceles right-angled triangle, having given the sum of the hypotenuse and one side

4 Construct a triangle, having given the perimeter and the angles at the base

[Let AB be the perimeter of the required Δ , and X and Y the \angle^s at the base

From A draw AP , making the $\angle BAP$ equal to half the $\angle X$

From B draw BP , making the $\angle ABP$ equal to half the $\angle Y$

From P draw PQ , making the $\angle APQ$ equal to the $\angle BAP$

From P draw PR , making the $\angle BPR$ equal to the $\angle ABP$

Then shall PQR be the required Δ]

5 Construct a right angled triangle, having given the perimeter and one acute angle

6 Construct an isosceles triangle of given altitude, so that its base may be in a given straight line, and its two equal sides may pass through two fixed points [Sec Ex 7, p 49]

7 Construct an equilateral triangle, having given the length of the perpendicular drawn from one of the vertices to the opposite side

8 Construct an isosceles triangle, having given the base, and the difference of one of the remaining sides and the perpendicular drawn from the vertex to the base [See Ex 1, p 88]

9 Construct a triangle, having given the base, one of the angles at the base, and the sum of the remaining sides

10 Construct a triangle, having given the base, one of the angles at the base, and the difference of the remaining sides

11 Construct a triangle, having given the base, the difference of the angles at the base, and the difference of the remaining sides

[Let AB be the given base, X the difference of the \angle 's at the base, and K the difference of the remaining sides

Draw BE, making the \angle ABE equal to half the \angle X

From centre A, with radius equal to K, describe a circle cutting BE in D and D'. Let D be the point of intersection nearer to B

Join AD and produce it to C

Draw BC, making the \angle DBC equal to the \angle BDC

Then shall CAB be the Δ required Ex 7, p 101

NOTE This problem is possible only when the given difference K is greater than the perpendicular drawn from A to BE]

12 Construct a triangle, having given the base, the difference of the angles at the base, and the sum of the remaining sides

13 Construct a triangle, having given the perpendicular from the vertex on the base, and the difference between each side and the adjacent segment of the base

14 Construct a triangle, having given two sides and the median which bisects the remaining side [See Ex 18, p. 102]

15 Construct a triangle, having given one side, and the medians which bisect the two remaining sides.

[See Fig to Ex. 4, p 105]

Let BC be the given side Take two-thirds of each of the given medians, hence construct the triangle BOC. The rest of the construction follows easily.]

16 Construct a triangle, having given its three medians

[See Fig. to Ex 4, p. 105]

Take two-thirds of each of the given medians, and construct the triangle OKC The rest of the construction follows easily]

VIII. ON AREAS

See Propositions 35—48

It must be understood that throughout this section the word *equal* as applied to rectilineal figures will be used as denoting *equality of area* unless otherwise stated.

1. Shew that a parallelogram is bisected by any straight line which passes through the middle point of one of its diagonals [I. 29, 26]

2 Bisect a parallelogram by a straight line drawn through a given point

3 Bisect a parallelogram by a straight line drawn perpendicular to one of its sides

4 Bisect a parallelogram by a straight line drawn parallel to a given straight line

5 ABCD is a trapezium in which the side AB is parallel to DC Shew that its area is equal to the area of a parallelogram formed by drawing through X, the middle point of BC, a straight line parallel to AD. [I 29, 26]

6 A trapezium is equal to a parallelogram whose base is half the sum of the parallel sides of the given figure, and whose altitude is equal to the perpendicular distance between them

7 ABCD is a trapezium in which the side AB is parallel to DC; shew that it is double of the triangle formed by joining the extremities of AD to X, the middle point of BC.

8. Shew that a trapezium is bisected by the straight line which joins the middle points of its parallel sides. [I 38]

In the following group of Exercises the proofs depend chiefly on Propositions 37 and 38, and the two converse theorems

9 If two straight lines AB , CD intersect at X , and if the straight lines AC and BD , which join their extremities are parallel, shew that the triangle AXD is equal to the triangle BXC

10 If two straight lines AB , CD intersect at X , so that the triangle AXD is equal to the triangle XCB , then AC and BD are parallel

11 $ABCD$ is a parallelogram, and X any point in the diagonal AC produced, shew that the triangles XBC , XDC are equal [See Ex 13, p 64]

12 ABC is a triangle, and R , Q the middle points of the sides AB , AC , shew that if BQ and CR intersect in X , the triangle BXC is equal to the quadrilateral $AQXR$ [See Ex 5, p 73]

13 If the middle points of the sides of a quadrilateral be joined in order, the *parallelogram* so formed [see Ex 9, p 97] is equal to half the given figure

14 Two triangles of equal area stand on the same base but on opposite sides of it shew that the straight line joining their vertices is bisected by the base, or by the base produced

15 The straight line which joins the middle points of the diagonals of a trapezium is parallel to each of the two parallel sides.

16 (i) *A triangle is equal to the sum or difference of two triangles on the same base (or on equal bases), if the altitude of the former is equal to the sum or difference of the altitudes of the latter*

(ii) *A triangle is equal to the sum or difference of two triangles of the same altitude if the base of the former is equal to the sum or difference of the bases of the latter*

Similar statements hold good of parallelograms

17 $ABCD$ is a parallelogram, and O is any point outside it, shew that the sum or difference of the triangles OAB , OCD is equal to half the parallelogram Distinguish between the two cases

On the following proposition depends an important theorem in Mechanics we give a proof of the first case, leaving the second case to be deduced by a similar method

18. (i) $ABCD$ is a parallelogram, and O is any point without the angle BAD and its opposite vertical angle, shew that the triangle OAC is equal to the sum of the triangles OAD , OAB

(ii) If O is within the angle BAD or its opposite vertical angle, the triangle OAC is equal to the difference of the triangles OAD , OAB

CASE I. If O is without the $\angle DAB$ and its opp. vert \angle , then OA is without the par^m $ABCD$. therefore the perp drawn from C to OA is equal to the sum of the perp^s drawn from B and D to OA [See Ex 20, p 99]

Now the Δ^s OAC , OAD , OAB are upon the same base OA , and the altitude of the Δ OAC with respect to this base has been shewn to be equal to the sum of the altitudes of the Δ^s OAD , OAB

Therefore the Δ OAC is equal to the sum of the Δ^s OAD , OAB
[See Ex 16, p 110]

19 $ABCD$ is a parallelogram, and through O , any point within it, straight lines are drawn parallel to the sides of the parallelogram, shew that the difference of the parallelograms DO , BO is double of the triangle AOC . [See preceding theorem (ii)]

20 The area of a quadrilateral is equal to the area of a triangle having two of its sides equal to the diagonals of the given figure, and the included angle equal to either of the angles between the diagonals

✓ 21 ABC is a triangle, and D is any point in AB it is required to draw through D a straight line DE to meet BC produced in E , so that the triangle DBE may be equal to the triangle ABC

[Join DC . Through A draw AE parallel to DC
Join DE .

1 31

The Δ EBD shall be equal to the Δ ABC

1 37]

22 On a base of given length describe a triangle equal to a given triangle and having an angle equal to an angle of the given triangle

23 Construct a triangle equal in area to a given triangle, and having a given altitude.

24 On a base of given length construct a triangle equal to a given triangle, and having its vertex on a given straight line

25 On a base of given length describe (i) an isosceles triangle, (ii) a right angled triangle, equal to a given triangle

26 Construct a triangle equal to the sum or difference of two given triangles [See Ex 16, p 110]

27 ABC is a given triangle, and X a given point describe a triangle equal to ABC, having its vertex at X, and its base in the same straight line as BC

28 ABCD is a quadrilateral on the base AB construct a triangle equal in area to ABCD, and having the angle at A common with the quadrilateral

[Join BD Through C draw CX parallel to BD, meeting AD produced in X, join BX]

29 Construct a rectilineal figure equal to a given rectilineal figure, and having fewer sides by one than the given figure

Hence shew how to construct a triangle equal to a given rectilineal figure

30 ABCD is a quadrilateral it is required to construct a triangle equal in area to ABCD, having its vertex at a given point X in DC, and its base in the same straight line as AB

31 Construct a rhombus equal to a given parallelogram

32 Construct a parallelogram which shall have the same area and perimeter as a given triangle

33 Bisect a triangle by a straight line drawn through one of its angular points

34 Trisect a triangle by straight lines drawn through one of its angular points [See Ex. 19, p 102, and 1 38⁴]

35 Divide a triangle into any number of equal parts by straight lines drawn through one of its angular points [See Ex 19, p 99, and 1 38]

[The following Theorems depend on 1 47]

41 In the figure of 1 47, shew that

- (i) the sum of the squares on AB and AE is equal to the sum of the squares on AC and AD
- (ii) the square on EK is equal to the square on AB with four times the square on AC.
- (iii) the sum of the squares on EK and FD is equal to five times the square on BC

42 If a straight line be divided into any two parts the square on the straight line is greater than the squares on the two parts

43 If the square on one side of a triangle is less than the squares on the remaining sides, the angle contained by these sides is acute, if greater, obtuse

44 ABC is a triangle, right-angled at A, the sides AB, AC are intersected by a straight line PQ, and BQ, PC are joined shew that the sum of the squares on BQ, PC is equal to the sum of the squares on BC, PQ

45 In a right angled triangle four times the sum of the squares on the medians which bisect the sides containing the right angle is equal to five times the square on the hypotenuse

46 Describe a square whose area shall be three times that of a given square

47 Divide a straight line into two parts such that the sum of their squares shall be equal to a given square.

IX. ON LOCI

It is frequently required in the course of Plane Geometry to find the position of a point which satisfies given conditions. Now all problems of this type hitherto considered have been found to be capable of definite determination, though some admit of more than one solution this however will not be the case if *only one* condition is given. For example, if we are asked to find a point which shall be at a given distance from a given point, we observe at once that the problem is *indeterminate*, that is, that it admits of an indefinite number of solutions, for the condition stated is satisfied by any point on the circumference of the circle described from the given point as centre, with a radius equal to the given distance moreover this condition is satisfied by no other point within or without the circle

Again, suppose that it is required to find a point at a given distance from a given straight line.

Here, too, it is obvious that there are an infinite number of such points, and that they lie on the two parallel straight lines which may be drawn on either side of the given straight line at the given distance from it: further, no point that is not on one or other of these parallels satisfies the given condition.

Hence we see that when one condition is assigned it is not sufficient to determine the position of a point absolutely, but it may have the effect of restricting it to some definite line or lines, straight or curved. This leads us to the following definition.

DEFINITION. The Locus of a point satisfying an assigned condition consists of the line, lines, or part of a line, to which the point is thereby restricted: provided that the condition is satisfied by every point on such line or lines, and by no other.

A locus is sometimes defined as the path traced out by a point which moves in accordance with an assigned law.

Thus the locus of a point, which is always at a given distance from a given point, is a circle of which the given point is the centre: and the locus of a point, which is always at a given distance from a given straight line, is a pair of parallel straight lines.

We now see that in order to infer that a certain line, or system of lines, is the locus of a point under a given condition, it is necessary to prove

- (i) that any point which fulfils the given condition is on the supposed locus;
- (ii) that every point on the supposed locus satisfies the given condition.

1. Find the locus of a point which is always equidistant from two given points.

Let A, B be the two given points.

(c) Let P be any point equidistant from A and B, so that $AP=BP$.

Bisect AB at X, and join PX.

Then in the Δ^s AXP, BXP,

Because $\begin{cases} AX=BX, \\ \text{and } PX \text{ is common to both,} \\ \text{also } AP=BP, \end{cases}$

\therefore the $\angle PXA = \text{the } \angle PXB$;
and they are adjacent \angle^s ;

\therefore PX is perp to AB

\therefore Any point which is equidistant from A and B is on the straight line which bisects AB at right angles

Constr.

Hyp.
i. 8.

(β) Also every point in this line is equidistant from A and B

For let Q be any point in this line

Join AQ, BQ

Then in the Δ^s AXQ, BXQ,

AX = BX,

Because { and XQ is common to both,
also the \angle AXQ = the \angle BXQ, being rt. \angle^s ,

AQ = BQ

1 4

That is, Q is equidistant from A and B

Hence we conclude that the locus of the point equidistant from two given points A, B is the straight line which bisects AB at right angles

2 To find the locus of the middle point of a straight line drawn from a given point to meet a given straight line of unlimited length

Let A be the given point, and BC the given straight line of unlimited length

(α) Let AX be any straight line drawn through A to meet BC, and let P be its middle point

Draw AF perp to BC, and bisect AF at E

Join EP, and produce it indefinitely

Since AFX is a Δ , and E, P the middle points of the two sides AF, AX,

EP is parallel to the remaining side FX Ex 2, p 96

P is on the straight line which passes through the fixed point E, and is parallel to BC

(β) Again, every point in EP, or EP produced, fulfils the required condition

For, in this straight line take any point Q

Join AQ, and produce it to meet BC in Y

Then FAY is a Δ , and through E, the middle point of the side AF, EQ is drawn parallel to the side FY,

Q is the middle point of AY

Ex 1, p 96.

Hence the required locus is the straight line drawn parallel to BC, and passing through E, the middle point of the perp from A to BC.

3 Find the locus of a point equidistant from two given intersecting straight lines [See Ex 3, p 49]

4 Find the locus of a point at a given radial distance from the circumference of a given circle

5 Find the locus of a point which moves so that the sum of its distances from two given intersecting straight lines of unlimited length is constant

6 Find the locus of a point when the differences of its distances from two given intersecting straight lines of unlimited length is constant

7. A straight rod of given length slides between two straight rulers placed at right angles to one another find the locus of its middle point [See Ex 2, p 100]

8 On a given base as hypotenuse right-angled triangles are described find the locus of their vertices

9. AB is a given straight line, and AX is the perpendicular drawn from A to any straight line passing through B find the locus of the middle point of AX

10 Find the locus of the vertex of a triangle, when the base and area are given

11 Find the locus of the intersection of the diagonals of a parallelogram, of which the base and area are given

12 Find the locus of the intersection of the medians of a triangle described on a given base and of given area

X. ON THE INTERSECTION OF LOCI.

It appears from various problems which have already been considered, that we are often required to find a point, the position of which is subject to two given conditions. The method of loci is very useful in the solution of problems of this kind for corresponding to each condition there will be a locus on which the required point must lie, hence all points which are common to these two loci, that is, all the points of intersection of the loci, will satisfy *both* the given conditions

EXAMPLE 1 To construct a triangle, having given the base, the altitude, and the length of the median which bisects the base

Let AB be the given base, and P and Q the lengths of the altitude and median respectively

then the triangle is known if its vertex is known

(i) Draw a straight line CD parallel to AB, and at a distance from it equal to P

then the required vertex must lie on CD

(ii) Again, from the middle point of AB as centre, with radius equal to Q, describe a circle

then the required vertex must lie on this circle

Hence any points which are common to CD and the circle, satisfy both the given conditions that is to say, if CD intersect the circle in E, F each of the points of intersection might be the vertex of the required triangle. Thus supposes the length of the median Q to be greater than the altitude

✓ **EXAMPLE 2** To find a point equidistant from three given points A, B, C, which are not in the same straight line

(i) The locus of points equidistant from A and B is the straight line PQ, which bisects AB at right angles Ex 1, p 115

(ii) Similarly the locus of points equidistant from B and C is the straight line RS which bisects BC at right angles

Hence the point common to PQ and RS must satisfy both conditions that is to say, the point of intersection of PQ and RS will be equidistant from A, B, and C

These principles may also be used to prove the theorems relating to concurrency already given on page 103

EXAMPLE To prove that the bisectors of the angles of a triangle are concurrent

Let ABC be a triangle

Bisect the \angle s ABC, BCA by straight lines BO, CO these must meet at some point O Ax 12

Join OA

Then shall OA bisect the \angle BAC

Now BO is the locus of points equidistant from BC, BA, Ex 3, p 19

$OP = OR$

Similarly CO is the locus of points equidistant from BC, CA

$OP = OQ$, hence $OR = OQ$

O is on the locus of points equidistant from AB and AC

that is OA is the bisector of the \angle BAC

Hence the bisectors of the three \angle s meet at the point O

It may happen that the data of the problem are so related to one another that the resulting loci do not intersect in this case the problem is impossible.

For example, if in Ex 1, page 118, the length of the given median *is less than* the given altitude, the straight line CD will not be intersected by the circle, and no triangle can fulfil the conditions of the problem. If the length of the median *is equal* to the given altitude, *one* point is common to the two loci, and consequently only one solution of the problem exists and we have seen that there are two solutions, if the median is greater than the altitude

In examples of this kind the student should make a point of investigating the relations which must exist among the data, in order that the problem may be possible, and he must observe that if under certain relations *two* solutions are possible, and under other relations no solution exists, there will always be some *intermediate* relation under which *one* and *only one* solution is possible

EXAMPLES

- 1 Find a point in a given straight line which is equidistant from two given points.
2. Find a point which is at given distances from each of two given straight lines. How many solutions are possible?
- 3 On a given base construct a triangle, having given one angle at the base and the length of the opposite side. Examine the relations which must exist among the data in order that there may be two solutions, one solution, or that the problem may be impossible
- 4 On the base of a given triangle construct a second triangle equal in area to the first, and having its vertex in a given straight line
- 5 Construct an isosceles triangle equal in area to a given triangle, and standing on the same base.
- 6 Find a point which is at a given distance from a given point, and is equidistant from two given parallel straight lines

BOOK II

BOOK II deals with the areas of rectangles and squares

DEFINITIONS

1 A Rectangle is a parallelogram which has one of its angles a right angle

It should be remembered that if a parallelogram has *one* right angle, *all* its angles are right angles [Ex 1, p 64]

2 A rectangle is said to be contained by any two of its sides which form a right angle for it is clear that both the form and magnitude of a rectangle are fully determined when the lengths of two such sides are given

Thus the rectangle ACDB is said to be contained by AB, AC, or by CD, DB and if X and Y are two straight lines equal respectively to AB and AC, then the rectangle contained by X and Y is equal to the rectangle contained by AB, AC

[See Ex 12, p 64]

After Proposition 3, we shall use the abbreviation *rect* AB, AC to denote the *rectangle contained by* AB and AC

3 In any parallelogram the figure formed by either of the parallelograms about a diagonal together with the two complements is called a gnomon

Thus the shaded portion of the annexed figure, consisting of the parallelogram EH together with the complements AK, KC is the *gnomon* AHF

The other gnomon in the figure is that which is made up of AK, GF and FH, namely the gnomon AFH

INTRODUCTORY.

Pure Geometry makes no use of *number* to estimate the magnitude of the lines, angles, and figures with which it deals. hence it requires no *units of magnitude* such as the student is familiar with in Arithmetic

For example, though Geometry is concerned with the relative lengths of straight lines, it does not seek to express those lengths in terms of *yards, feet, or inches* similarly it does not ask how many *square yards* or *square feet* a given figure contains, nor how many *degrees* there are in a given angle

This constitutes an essential difference between the method of Pure Geometry and that of Arithmetic and Algebra, at the same time a close connection exists between the results of these two methods

In the case of Euclid's Book II, this connection rests upon the fact that *the number of units of area in a rectangular figure is found by multiplying together the numbers of units of length in two adjacent sides*

For example, if the two sides AB, AD of the rectangle ABCD are respectively *four* and *three* inches long, and if through the points of division parallels are drawn as in the annexed figure, it is seen that the rectangle is divided into *three rows*, each containing *four* square inches, or into *four columns*, each containing *three* square inches

Hence the whole rectangle contains 3×4 , or 12, square inches

Similarly if AB and AD contain m and n units of length respectively, it follows that the rectangle ABCD will contain mn units of area further, if AB and AD are equal, each containing m units of length, the rectangle becomes a square, and contains m^2 units of area

[It must be understood that this explanation implies that the lengths of the straight lines AB, AD are commensurable, that is, that they can be expressed *exactly* in terms of some common unit

This however is not always the case for example, it may be proved that the side and diagonal of a square are so related, that it is impossible to divide either of them into equal parts, *of which the other contains an exact number* Such lines are said to be incommen-

surable Hence if the adjacent sides of a rectangle are incommensurable, we cannot choose any linear unit in terms of which these sides may be *exactly* expressed, and thus it will be impossible to subdivide the rectangle into squares of unit area, as illustrated in the figure of the preceding page We do not here propose to enter further into the subject of incommensurable quantities it is sufficient to point out that further knowledge of them will convince the student that the area of a rectangle may be expressed to *any required degree of accuracy* by the product of the lengths of two adjacent sides, whether those lengths are commensurable or not]

From the foregoing explanation we conclude that *the rectangle contained by two straight lines* in Geometry corresponds to *the product of two numbers* in Arithmetic or Algebra, and that *the square described on a straight line* corresponds to *the square of a number* Accordingly it will be found in the course of Book II that several theorems relating to the areas of rectangles and squares are analogous to well-known algebraical formulæ

In view of these principles the rectangle contained by two straight lines AB, BC is sometimes expressed in the form of a product, as AB BC, and the square described on AB as AB^2 This notation, together with the signs + and -, will be employed in the additional matter appended to this book, *but it is not admitted into Euclid's text* because it is desirable in the first instance to emphasize the distinction between geometrical magnitudes themselves and the numerical equivalents by which they may be expressed arithmetically

PROPOSITION I THEOREM

If there are two straight lines, one of which is divided into any number of parts, the rectangle contained by the two straight lines is equal to the sum of the rectangles contained by the undivided straight line and the several parts of the divided line

Let P and AB be two straight lines, and let AB be divided into any number of parts AC, CD, DB

then shall the rectangle contained by P, AB be equal to the sum of the rectangles contained by P, AC, by P, CD, and by P, DB

From A draw AF perp to AB, I 11.
and make AG equal to P. I 3.

Through G draw GH par^l to AB, I 31
and through C, D, B draw CK, DL, BH par^l to AG

Now the fig AH is made up of the figs AK, CL, DH
and of these,

the fig AH is the rectangle contained by P, AB,
for the fig AH is contained by AG, AB, and AG = P;
and the fig AK is the rectangle contained by P, AC;
for the fig AK is contained by AG, AC, and AG = P
also the fig CL is the rectangle contained by P, CD;

for the fig CL is contained by CK, CD;
and CK = the opp side AG, and AG = P I 34

similarly the fig DH is the rectangle contained by P, DB

∴ the rectangle contained by P, AB is equal to the
sum of the rectangles contained by P, AC, by P, CD, and
by P, DB Q E D

CORRESPONDING ALGEBRAICAL FORMULA

In accordance with the principles explained on page 122, the result
of this proposition may be written thus

$$P \cdot AB = P \cdot AC + P \cdot CD + P \cdot DB.$$

Now if the line P contains p units of length, and if AC, CD, DB
contain a , b , c units respectively,

$$\text{then } AB = a + b + c,$$

and we have

$$p(a + b + c) = pa + pb + pc$$

PROPOSITION 2 THEOREM

If a straight line is divided into any two parts, the square on the whole line is equal to the sum of the rectangles contained by the whole line and each of the parts

Let the straight line AB be divided at C into the two parts AC, CB

then shall the sq on AB be equal to the sum of the rects contained by AB, AC, and by AB, BC

On AB describe the square ADEB I 46

Through C draw CF par^l to AD J 31

Now the fig AE is made up of the figs AF, CE and of these,

the fig AE is the sq on AB *Constr*
 and the fig AF is the rectangle contained by AB, AC,
 for the fig AF is contained by AD, AC, and AD=AB;
 also the fig CE is the rectangle contained by AB, BC,
 for the fig CE is contained by BE, BC, and BE=AB

the sq on AB = the sum of the rects contained by AB, AC, and by AB, BC Q E.D

CORRESPONDING ALGEBRAICAL FORMULA

The result of this proposition may be written

$$AB^2 = AB \cdot AC + AB \cdot BC$$

Let AC contain a units of length, and let CB contain b units,

$$\text{then } AB = a + b,$$

and we have

$$(a + b)^2 = (a + b)a + (a + b)b$$

PROPOSITION 3 THEOREM

If a straight line is divided into any two parts, the rectangle contained by the whole and one of the parts is equal to the square on that part together with the rectangle contained by the two parts

Let the straight line AB be divided at C into the two parts AC, CB

then shall the rect contained by AB, AC be equal to the sq on AC together with the rect contained by AC, CB

On AC describe the square AFDC, I 46
and through B draw BE par^l to AF, meeting FD produced in E I 31

Now the fig AE is made up of the figs AD, CE,
and of these,

the fig AE = the rect contained by AB, AC,
for AF = AC,

and the fig AD is the sq on AC, Constr.

also the fig CE is the rect contained by AC, CB,
for CD = AC.

the rect contained by AB, AC is equal to the sq on AC together with the rect contained by AC, CB Q E D

CORRESPONDING ALGEBRAICAL FORMULA

This result may be written $AB \cdot AC = AC^2 + AC \cdot CB$

Let AC, CB contain a and b units of length respectively,

then $AB = a + b$,

and we have

$$(a + b)a = a^2 + ab$$

NOTE It should be observed that Props. 2 and 3 are special cases of Prop. 1

PROPOSITION 4 THEOREM.

If a straight line is divided into any two parts, the square on the whole line is equal to the sum of the squares on the two parts together with twice the rectangle contained by the two parts

Let the straight line AB be divided at C into the two parts AC, CB

then shall the sq on AB be equal to the sum of the sqq on AC, CB, together with twice the rect AC, CB

On AB describe the square ADEB, I 46
and join BD

Through C draw CF par^l to BE, meeting BD in G I 31

Through G draw HGK par^l to AB

It is first required to shew that the fig CK is the sq on BC

Because the straight line BGD meets the par^{ls} CG, AD,
the ext angle CGB = the int opp angle ADB I 29

But AB = AD, being sides of a square,
the angle ADB = the angle ABD; I 5
the angle CGB = the angle CBG

CB = CG I 6

And the opp sides of the par^m CK are equal, I 34.
the fig CK is equilateral,

and the angle CBK is a right angle, Def 28.

∴ CK is a square, and it is described on BC I 46, Cor

Similarly the fig HF is the sq. on HG, that is, the sq on AC,

for HG = the opp side AC I. 34.

Again, the complement AG = the complement GE I 43

But the fig AG = the rect AC, CB, for CG = CB

. the two figs. AG, GE = twice the rect AC, CB

*Now the sq on AB = the fig AE

= the figs HF, CK, AG, GE

= the sqq on AC, CB together with
twice the rect AC, CB

the sq on AB = the sum of the sqq on AC, CB with
twice the rect AC, CB Q E D

* For the purpose of oral work, this step of the proof may conveniently be arranged as follows

Now the sq on AB is equal to the fig AE,

that is, to the figs HF, CK, AG, GE,

that is, to the sqq on AC, CB together
with twice the rect AC, CB

COROLLARY. *Parallelograms about the diagonals of a square are themselves squares*

CORRESPONDING ALGEBRAICAL FORMULA

The result of this important Proposition may be written thus

$$AB^2 = AC^2 + CB^2 + 2AC \cdot CB$$

Let

$$AC = a, \text{ and } CB = b,$$

$$\text{then } AB = a + b,$$

and we have

$$(a + b)^2 = a^2 + b^2 + 2ab$$

PROPOSITION 5 THEOREM

If a straight line is divided equally and also unequally, the rectangle contained by the unequal parts, and the square on the line between the points of section, are together equal to the square on half the line

Let the straight line AB be divided equally at P, and unequally at Q

then the rect. AQ, QB and the sq on PQ shall be together equal to the sq on PB

On PB describe the square PCDB 1 46

Join BC

Through Q draw QE par^l to BD, cutting BC in F 1 31

Through F draw LFHG par^l to AB

Through A draw AG par^l to BD

Now the complement PF = the complement FD 1 43

to each add the fig QL,

then the fig PL = the fig QD

But the fig PL = the fig AH, for they are par^{ms} on equal bases and between the same par^{ls} 1 36

the fig AH = the fig QD

To each add the fig PF,

then the fig AF = the gnomon PLE

Now the fig AF = the rect. AQ, QB, for QB = QF,

the rect. AQ, QB = the gnomon PLE

To each add the sq on PQ, that is, the fig HE, 11 4
then the rect. AQ, QB with the sq on PQ

= the gnomon PLE with the fig HE

= the whole fig PD,

which is the sq on PB

That is, the rect AQ, QB and the sq on PQ are together equal to the sq on PB

Q E D

COROLLARY From this Proposition it follows that the difference of the squares on two straight lines is equal to the rectangle contained by their sum and difference

For let X and Y be the given st lines, of which X is the greater

Draw AP equal to X, and produce it to B, making PB equal to AP, that is to X

From PB cut off PQ equal to Y.

Then AQ is equal to the sum of X and Y,

and QB is equal to the difference of X and Y

Now because AB is divided equally at P and unequally at Q,

the rect AQ, QB with sq on PQ = the sq on PB, II 5
that is, the difference of the sqq on PB, PQ = the rect AQ, QB,
or, the difference of the sqq on X and Y = the rect contained by the sum and the difference of X and Y

CORRESPONDING ALGEBRAICAL FORMULA

This result may be written

$$AQ \cdot QB + PQ^2 = PB^2.$$

Let $AB = 2a$, and let $PQ = b$,

then AP and PB each = a

Also $AQ = a + b$, and $QB = a - b$

Hence we have

$$(a + b)(a - b) + b^2 = a^2,$$

or

$$(a + b)(a - b) = a^2 - b^2.$$

EXERCISE

In the above figure shew that AP is half the sum of AQ and QB; and that PQ is half their difference

PROPOSITION 6 THEOREM

If a straight line is bisected and produced to any point, the rectangle contained by the whole line thus produced, and the part of it produced, together with the square on half the line bisected, is equal to the square on the straight line made up of the half and the part produced

Let the straight line AB be bisected at P, and produced to Q
 then the rect AQ, QB and the sq on PB shall be together equal to the sq on PQ.

On PQ describe the square PCDQ.

Join QC

Through B draw BE par^l to QD, meeting QC in F I 46

Through F draw LFHG par^l to AQ I 31

Through A draw AG par^l to QD

Now the complement PF = the complement FD I 43

But the fig PF = the fig AH, for they are par^{ms} on equal bases and between the same par^{ls} I 36

the fig AH = the fig FD

To each add the fig PL,

then the fig AL = the rect. AQ, QB, for QB = QL,

Now the fig AL = the rect. AQ, QB, that is, the fig HE,

the rect. AQ, QB with the sq on PB

= the gnomon PLE with the fig HE

= the whole fig PD,

which is the square on PQ

That is, the rect AQ, QB and the sq on PB are together equal to the sq on PQ.

Q E.D.

CORRESPONDING ALGEBRAICAL FORMULA

This result may be written

$$AQ \cdot QB + PB^2 = PQ^2$$

Let $AB = 2a$, and let $PQ = b$,

then AP and PB each $= a$

Also $AQ = a + b$, and $QB = b - a$

Hence we have

$$(a + b)(b - a) + a^2 = b^2,$$

or

$$(b + a)(b - a) = b^2 - a^2$$

DEFINITION If a point X is taken in a straight line AB , or in AB produced, the distances of the point of section from the extremities of AB are said to be the segments into which AB is divided at X

In the former case AB is divided internally, in the latter case externally

Thus in the annexed figures the segments into which AB is divided at X are the lines XA and XB

This definition enables us to include Props. 5 and 6 in a single Enunciation

If a straight line is bisected, and also divided (internally or externally) into two unequal segments, the rectangle contained by the unequal segments is equal to the difference of the squares on half the line, and on the line between the points of section

EXERCISE

Shew that the Enunciations of Props 5 and 6 may take the following form

The rectangle contained by two straight lines is equal to the difference of the squares on half their sum and on half their difference

[See Ex, p 129]

PROPOSITION 7 THEOREM

If a straight line is divided into any two parts, the sum of the squares on the whole line and on one of the parts is equal to twice the rectangle contained by the whole and that part, together with the square on the other part

Let the straight line AB be divided at C into the two parts AC, CB

then shall the sum of the sqq on AB, BC be equal to twice the rect. AB, BC together with the sq on AC

On AB describe the square ADEB I 46

Join BD

Through C draw CF par^l to BE, meeting BD in G I 31

Through G draw HGK par^l to AB

Now the complement AG = the complement GE, I 43
to each add the fig CK

then the fig AK = the fig CE

But the fig AK = the rect AB, BC, for BK = BC

the two figs AK, CE = twice the rect AB, BC

But the two figs AK, CE make up the gnomon AKF and the fig CK

the gnomon AKF with the fig CK = twice the rect AB, BC

To each add the fig HF, which is the sq on AC

then the gnomon AKF with the figs CK, HF

= twice the rect AB, BC with the sq on AC

Now the sqq on AB, BC = the figs. AE, CK

= the gnomon AKF with the figs CK, HF

= twice the rect. AB, BC with the sq on AC

CORRESPONDING ALGEBRAICAL FORMULA

The result of this proposition may be written

$$AB^2 + BC^2 = 2AB \cdot BC + AC^2$$

Let $AB = a$, and $BC = b$, then $AC = a - b$

Hence we have $a^2 + b^2 = 2ab + (a - b)^2$,

or

$$(a - b)^2 = a^2 - 2ab + b^2.$$

PROPOSITION 8 THEOREM

If a straight line be divided into any two parts, four times the rectangle contained by the whole line and one of the parts, together with the square on the other part, is equal to the square on the straight line which is made up of the whole and that part

[As this proposition is of little importance we merely give the figure, and the leading points in Euclid's proof]

Let AB be divided at C

Produce AB to D , making BD equal to BC

On AD describe the square $AEFD$, and complete the construction as indicated in the figure

Euclid then proves (i) that the figs CK, BN, GR, KO are all equal

(ii) that the figs AG, MP, PL, RF are all equal

Hence the eight figures named above are four times the sum of the figs AG, CK , that is, four times the fig AK , that is, four times the rect AB, BC

But the whole fig AF is made up of these eight figures, together with the fig XH , which is the sq on AC

hence the sq. on $AD =$ four times the rect AB, BC , together with the sq on AC

The accompanying figure will suggest a less cumbrous proof, which we leave as an Exercise to the student.

$$(a+b)^2 - (a-b)^2 = 4ab$$

PROPOSITION 9 THEOREM

If a straight line is divided equally and also unequally, the sum of the squares on the two unequal parts is twice the sum of the squares on half the line and on the line between the points of section

Let the straight line AB be divided equally at P, and unequally at Q

then shall the sum of the sqq on AQ, QB be twice the sum of the sqq on AP, PQ.

At P draw PC at rt angles to AB, I 11
and make PC equal to AP or PB I 3

Join AC, BC

Through Q draw QD par^l to PC, I 31
and through D draw DE par^l to AB

Join AD

Then since PA = PC, *Constr*
the angle PAC = the angle PCA I 5

And since, in the triangle APC, the angle APC is a rt angle, *Constr*

the sum of the angles PAC, PCA is a rt. angle I 32

hence each of the angles PAC, PCA is half a rt angle

So also, each of the angles PBC, PCB is half a rt. angle

∴ the whole angle ACB is a rt angle

Again, the ext angle CED = the int opp angle CPB, I 29
the angle CED is a rt angle.

and the angle ECD is half a rt angle *Proved*

also the angle EDC is half a rt angle, I 32

the angle ECD = the angle EDC,

EC = ED

I 6

Again, the ext angle $DQB =$ the int opp angle CPB . I. 29.

\therefore the angle DQB is a rt angle

And the angle QBD is half a rt angle, *Proved*

\therefore also the angle QDB is half a rt angle I. 32

\therefore the angle $QBD =$ the angle QDB ,

$\therefore QD = QB$. I. 6.

Now the sq on $AP =$ the sq on PC , for $AP = PC$ *Constr*

But the sq. on $AC =$ the sum of the sqq. on AP, PC ,

for the angle APC is a rt angle I. 47.

the sq on AC is twice the sq on AP

So also, the sq on CD is twice the sq on ED , that is, twice the sq on the opp. side PQ . I. 34

Now the sqq on $AQ, QB =$ the sqq on AQ, QD

$=$ the sq on AD , for AQD is a rt angle, I. 47

$=$ the sum of the sqq on AC, CD , for ACD is a rt angle; I. 47

$=$ twice the sq on AP with twice the sq on PQ *Proved*

That is,

the sum of the sqq on $AQ, QB =$ twice the sum of the sqq on AP, PQ QED

CORRESPONDING ALGEBRAICAL FORMULA

The result of this proposition may be written

$$AQ^2 + QB^2 = 2(AP^2 + PQ^2)$$

Let $AB = 2a$, and $PQ = b$,

then AP and PB each $= a$

Also $AQ = a + b$, and $QB = a - b$

Hence we have

$$(a + b)^2 + (a - b)^2 = 2(a^2 + b^2)$$

PROPOSITION 10 THEOREM

If a straight line is bisected and produced to any point, the sum of the squares on the whole line thus produced, and on the part produced, is twice the sum of the squares on half the line bisected and on the line made up of the half and the part produced

Let the st line AB be bisected at P, and produced to Q
then shall the sum of the sqq on AQ, QB be twice the
sum of the sqq on AP, PQ.

At P draw PC at right angles to AB, I 11

and make PC equal to PA or PB I 3

Join AC, BC

Through Q draw QD par^l to PC, to meet CB produced
in D, I 31

and through D draw DE par^l to AB, to meet CP produced
in E

Join AD

Then since PA = PC, Constr

the angle PAC = the angle PCA I 5

And since in the triangle APC, the angle APC is a rt angle,

the sum of the angles PAC, PCA is a rt angle I 32

Hence each of the angles PAC, PCA is half a rt. angle

So also, each of the angles PBC, PCB is half a rt angle

the whole angle ACB is a rt angle

Again, the ext angle CPB = the int opp angle CED I 29

the angle CED is a rt angle

and the angle ECD is half a rt angle Proved

the angle EDC is half a rt angle I 32

the angle ECD = the angle EDC,

EC = ED I 6

Again, the angle $DQB =$ the alt angle CPB I 29.

∴ the angle DQB is a rt angle

Also the angle $QBD =$ the vert opp angle CBP , I 15.

that is, the angle QBD is half a rt angle

∴ the angle QDB is half a rt angle. I 32

∴ the angle $QBD =$ the angle QDB ;

$QB = QD$

I. 6

Now the sq on $AP =$ the sq on PC , for $AP = PC$. *Const*

But the sq on $AC =$ the sum of the sqq on AP, PC ,

for the angle APC is a rt angle I 47

the sq on AC is twice the sq on AP

So also, the sq on CD is twice the sq on ED , that is,
twice the sq on the opp side PQ . I 34

Now the sqq on $AQ, QB =$ the sqq on AQ, QD

$=$ the sq on AD , for AQD is a rt
angle, I 47

$=$ the sum of the sqq on AC, CD ,
for ACD is a rt angle; I 47

$=$ twice the sq on AP with twice
the sq on PQ . *Proved*

That is,

the sum of the sqq on AQ, QB is twice the sum of the sqq
on AP, PQ . Q E D

CORRESPONDING ALGEBRAICAL FORMULA.

The result of this proposition may be written

$$AQ^2 + BQ^2 = 2(AP^2 + PQ^2)$$

Let $AB = 2a$, and $PQ = b$,

then AP and PB each $= a$.

Also $AQ = a + b$, and $BQ = b - a$

Hence we have

$$(a + b)^2 + (b - a)^2 = 2(a^2 + b^2)$$

EXERCISE

Shew that the enunciations of Props 9 and 10 may take the following form

The sum of the squares on two straight lines is equal to twice the sum of the squares on half their sum and on half their difference

PROPOSITION 11. PROBLEM

To divide a given straight line into two parts, so that the rectangle contained by the whole and one part may be equal to the square on the other part

Let AB be the given straight line

It is required to divide it into two parts, so that the rectangle contained by the whole and one part may be equal to the square on the other part

On AB describe the square ACDB I 46

Bisect AC at E I 10

Join EB

Produce CA to F, making EF equal to EB I 3

On AF describe the square AFGH I 46

Then shall AB be divided at H, so that the rect AB, BH is equal to the sq on AH

Produce GH to meet CD in K

Then because CA is bisected at E, and produced to F,
the rect CF, FA with the sq on AE = the sq on FE II 6
= the sq on EB Constr

But the sq on EB = the sum of the sqq on AB, AE,
for the angle EAB is a rt angle I 47

the rect CF, FA with the sq on AE = the sum of the sqq on AB, AE.

From these take the sq on AE
then the rect CF, FA = the sq on AB

But the rect CF, $FA =$ the fig FK; for $FA = FG$,
 and the sq on AB = the fig AD *Constr*
 . the fig FK = the fig AD

From these take the common fig AK,
 then the remaining fig FH = the remaining fig HD.

But the fig HD = the rect AB, BH, for $BD = AB$,
 and the fig FH is the sq on AH
 . the rect AB, BH = the sq on AH Q.E.F

DEFINITION A straight line is said to be divided in Medial Section when the rectangle contained by the given line and one of its segments is equal to the square on the other segment

The student should observe that this division may be *internal* or *external*

Thus if the straight line AB is divided internally at H, and externally at H', so that

(i) $AB \cdot BH = AH^2$,
 (ii) $AB \cdot BH' = AH^2$, 

we shall in either case consider that AB is divided in medial section

The case of *internal* section is alone given in Euclid II 11, but a straight line may be divided *externally* in medial section by a similar process See Ex 21, p 146

ALGEBRAICAL ILLUSTRATION.

It is required to find a point H in AB, or AB produced, such that
 $AB \cdot BH = AH^2$

Let AB contain a units of length, and let AH contain x units,
 then $HB = a - x$

and x must be such that $a(a - x) = x^2$,
 or $x^2 + ax - a^2 = 0$

Thus the construction for dividing a straight line in medial section corresponds to the algebraical solution of this quadratic equation

EXERCISES

In the figure of II 11, shew that

- (i) if CH is produced to meet BF at L, CL is at right angles to BF.
- (ii) if BE and CH meet at O, AO is at right angles to CH.
- (iii) the lines BG, DF, AK are parallel.
- (iv) CF is divided in medial section at A.

PROPOSITION 12 THEOREM.

In an obtuse angled triangle, if a perpendicular is drawn from either of the acute angles to the opposite side produced, the square on the side subtending the obtuse angle is greater than the squares on the sides containing the obtuse angle, by twice the rectangle contained by the side on which, when produced, the perpendicular falls, and the line intercepted without the triangle, between the perpendicular and the obtuse angle

Let ABC be an obtuse-angled triangle, having the obtuse angle at C, and let AD be drawn from A perp to BC produced

then shall the sq on AB be greater than the sqq on BC, CA, by twice the rect BC, CD

Because BD is divided into two parts at C,
the sq on BD = the sum of the sqq on BC, CD, with twice
the rect BC, CD II 4

To each add the sq on DA

Then the sqq on BD, DA = the sum of the sqq on BC, CD, DA, with twice the rect BC, CD

But the sum of the sqq on BD, DA = the sq on AB,
for the angle at D is a rt angle I 47

Similarly the sum of the sqq on CD, DA = the sq on CA

the sq on AB = the sum of the sqq on BC, CA, with
twice the rect BC, CD

That is, the sq on AB is greater than the sum of the
sqq on BC, CA by twice the rect BC, CD Q E D

[For alternative Enunciations to Props 12 and 13 and Exercises,
see p 142]

PROPOSITION 13. THEOREM

In every triangle the square on the side subtending an acute angle, is less than the squares on the sides containing that angle, by twice the rectangle contained by either of these sides, and the straight line intercepted between the perpendicular let fall on it from the opposite angle, and the acute angle

Fig 1.

Fig 2

Let ABC be any triangle having the angle at B an acute angle, and let AD be the perp drawn from A to the opp. side BC :

then shall the sq on AC be less than the sum of the sqq on AB, BC, by twice the rect CB, BD

Now AD may fall within the triangle ABC, as in Fig 1, or without it, as in Fig 2.

Because { in Fig 1 BC is divided into two parts at D,
 { in Fig 2 BD is divided into two parts at C,
 in both cases,

the sum of the sqq on CB, BD = twice the rect CB, BD with the sq on CD. II. 7

To each add the sq on DA

Then the sum of the sqq. on CB, BD, DA = twice the rect CB, BD with the sum of the sqq on CD, DA.

But the sum of the sqq on BD, DA = the sq on AB,

for the angle ADB is a rt angle I 47.

Similarly the sum of the sqq on CD, DA = the sq on AC

∴ the sum of the sqq. on AB, BC, = twice the rect CB, BD, with the sq. on AC.

That is, the sq on AC is less than the sqq on AB, BC by twice the rect. CB, BD. Q E D.

Obs If the perpendicular AD coincides with AC, that is, if ACB is a right angle, it may be shewn that the proposition merely repeats the result of 1 47

NOTE The result of Prop 12 may be written

$$AB^2 = BC^2 + CA^2 + 2BC \cdot CD$$

Remembering the definition of the Projection of a straight line given on page 97, the student will see that this proposition may be enunciated as follows

In an obtuse angled triangle the square on the side opposite the obtuse angle is greater than the sum of the squares on the sides containing the obtuse angle by twice the rectangle contained by either of those sides, and the projection of the other side upon it

Prop 13 may be written

$$AC^2 = AB^2 + BC^2 - 2CB \cdot BD,$$

and it may also be enunciated as follows

In every triangle the square on the side subtending an acute angle, is less than the squares on the sides containing that angle, by twice the rectangle contained by either of these sides, and the projection of the other side upon it

EXERCISES

The following theorem should be noticed, it is proved by the help of II 1

1 If four points A, B, C, D are taken in order on a straight line, then will

$$AB \cdot CD + BC \cdot AD = AC \cdot BD$$

ON II 12 AND 13

2 If from one of the base angles of an isosceles triangle a perpendicular is drawn to the opposite side, then twice the rectangle contained by that side and the segment adjacent to the base is equal to the square on the base

3 If one angle of a triangle is one third of two right angles, shew that the square on the opposite side is less than the sum of the squares on the sides forming that angle, by the rectangle contained by these two sides [See Ex 10, p 101]

4. If one angle of a triangle is two-thirds of two right angles, shew that the square on the opposite side is greater than the squares on the sides forming that angle, by the rectangle contained by these sides [See Ex 10, p 101]

PROPOSITION 14 PROBLEM

To describe a square that shall be equal to a given rectilinear figure

Let A be the given rectilinear figure

It is required to describe a square equal to A

Describe the par^m BCDE equal to the fig A, and having the angle CBE a right angle I 45

Then if $BC = BE$, the fig BD is a square, and what was required is done

But if not, produce BE to F, making EF equal to ED, I 3
and bisect BF at G I 10.

From centre G, with radius GF, describe the semicircle BHF
produce DE to meet the semicircle at H

Then shall the sq on EH be equal to the given fig A

Join GH

Then because BF is divided equally at G and unequally at E,

the rect BE, EF with the sq on GE = the sq on GF II 5
= the sq on GH

But the sq on GH = the sum of the sqq on GE, EH,
for the angle HEG is a rt angle I 47

the rect BE, EF with the sq on GE = the sum of the sqq on GE, EH.

From these take the sq on GE:

then the rect BE, EF = the sq on HE

But the rect BE, EF = the fig BD; for $EF = ED$, Constr.
and the fig BD = the given fig A. Constr.

\therefore the sq. on EH = the given fig A. Q E F.

THEOREMS AND EXAMPLES ON BOOK II

ON II 1 AND 7

1 *Shew by II 4 that the square on a straight line is four times the square on half the line*

[This result is constantly used in solving examples on Book II, especially those which follow from II 12 and 18]

2 *If a straight line is divided into any three parts, the square on the whole line is equal to the sum of the squares on the three parts together with twice the rectangles contained by each pair of these parts*

Shew that the algebraical formula corresponding to this theorem is

$$(a + b + c)^2 = a^2 + b^2 + c^2 + 2bc + 2ca + 2ab$$

3 *In a right angled triangle, if a perpendicular is drawn from the right angle to the hypotenuse, the square on this perpendicular is equal to the rectangle contained by the segments of the hypotenuse*

4 *In an isosceles triangle, if a perpendicular be drawn from one of the angles at the base to the opposite side, shew that the square on the perpendicular is equal to twice the rectangle contained by the segments of that side together with the square on the segment adjacent to the base*

5 *Any rectangle is half the rectangle contained by the diagonals of the squares described upon its two sides*

6 *In any triangle if a perpendicular is drawn from the vertical angle to the base, the sum of the squares on the sides forming that angle, together with twice the rectangle contained by the segments of the base, is equal to the square on the base together with twice the square on the perpendicular*

ON II 5 AND 6

The student is reminded that these important propositions are both included in the following enunciation

The difference of the squares on two straight lines is equal to the rectangle contained by their sum and difference

7 *In a right-angled triangle the square on one of the sides forming the right angle is equal to the rectangle contained by the sum and difference of the hypotenuse and the other side. [I 47 and II 5]*

8 *The difference of the squares on two sides of a triangle is equal to twice the rectangle contained by the base and the intercept between the middle point of the base and the foot of the perpendicular drawn from the vertical angle to the base*

Let ABC be a triangle, and let P be the middle point of the base BC. let AQ be drawn perp to BC

Then shall $AB^2 - AC^2 = 2BC \cdot PQ$

First, let AQ fall within the triangle.

$$\text{Now } AB^2 = BQ^2 + QA^2,$$

r 47

$$\text{also } AC^2 = QC^2 + QA^2,$$

$$AB^2 - AC^2 = BQ^2 - QC^2$$

Ax 3

$$= (BQ + QC)(BQ - QC)$$

II 5

$$= BC \cdot 2PQ$$

Ex 1, p 129

$$= 2BC \cdot PQ$$

Q E D

The case in which AQ falls outside the triangle presents no difficulty.

9 *The square on any straight line drawn from the vertex of an isosceles triangle to the base is less than the square on one of the equal sides by the rectangle contained by the segments of the base.*

10 *The square on any straight line drawn from the vertex of an isosceles triangle to the base produced, is greater than the square on one of the equal sides by the rectangle contained by the segments into which the base is divided externally*

11 *If a straight line is drawn through one of the angles of an equilateral triangle to meet the opposite side produced, so that the rectangle contained by the segments of the base is equal to the square on the side of the triangle; shew that the square on the line so drawn is double of the square on a side of the triangle*

12 *If XY be drawn parallel to the base BC of an isosceles triangle ABC, then the difference of the squares on BY and CY is equal to the rectangle contained by BC, XY* [See above, Ex 8]

13 *In a right-angled triangle, if a perpendicular be drawn from the right angle to the hypotenuse, the square on either side forming the right angle is equal to the rectangle contained by the hypotenuse and the segment of it adjacent to that side.*

ON II 9 AND 10

14 Deduce Prop 9 from Props 4 and 5, using also the theorem that the square on a straight line is four times the square on half the line

15 Deduce Prop 10 from Props 7 and 6, using also the theorem mentioned in the preceding Exercise.

16 If a straight line is divided equally and also unequally, the squares on the two unequal segments are together equal to twice the rectangle contained by these segments together with four times the square on the line between the points of section

ON II 11

17 If a straight line is divided internally in medial section, and from the greater segment a part be taken equal to the less, shew that the greater segment is also divided in medial section

18 If a straight line is divided in medial section, the rectangle contained by the sum and difference of the segments is equal to the rectangle contained by the segments

19 If AB is divided at H in medial section, and if X is the middle point of the greater segment AH, shew that a triangle whose sides are equal to AH, XH, BX respectively must be right-angled.

20 If a straight line AB is divided internally in medial section at H, prove that the sum of the squares on AB, BH is three times the square on AH.

21 Divide a straight line externally in medial section

[Proceed as in II 11, but instead of drawing EF, make EF' equal to EB in the direction remote from A, and on AF' describe the square AF'G'H' on the side remote from AB. Then AB will be divided externally at H as required.]

ON II 12 AND 13

22 In a triangle ABC the angles at B and C are acute. If E and F are the feet of perpendiculars drawn from the opposite angles to the sides AC, AB, shew that the square on BC is equal to the sum of the rectangles AB, BF and AC, CE.

23 ABC is a triangle right-angled at C, and DE is drawn from a point D in AC perpendicular to AB. shew that the rectangle AB, AE is equal to the rectangle AC, AD

24 In any triangle the sum of the squares on two sides is equal to twice the square on half the third side together with twice the square on the median which bisects the third side

Let ABC be a triangle, and AP the median bisecting the side BC
Then shall $AB^2 + AC^2 = 2BP^2 + 2AP^2$

Draw AQ perp to BC

Consider the case in which AQ falls within the triangle, but does not coincide with AP.

Then of the angles APB, APC, one must be obtuse, and the other acute. let APB be obtuse

Then in the $\triangle APB$, $AB^2 = BP^2 + AP^2 + 2BP \cdot PQ$ II 12

Also in the $\triangle APC$, $AC^2 = CP^2 + AP^2 - 2CP \cdot PQ$ II 13

But $CP = BP$,

$CP^2 = BP^2$, and the rect BP, PQ = the rect CP, PQ

Hence adding the above results

$AB^2 + AC^2 = 2 \cdot BP^2 + 2 \cdot AP^2$

QED

The student will have no difficulty in adapting this proof to the cases in which AQ falls without the triangle, or coincides with AP.

✓ 25 The sum of the squares on the sides of a parallelogram is equal to the sum of the squares on the diagonals

✓ 26 In any quadrilateral the squares on the diagonals are together equal to twice the sum of the squares on the straight lines joining the middle points of opposite sides [See Ex 9, p 97.]

✓ 27. If from any point within a rectangle straight lines are drawn to the angular points, the sum of the squares on one pair of the lines drawn to opposite angles is equal to the sum of the squares on the other pair.

28 The sum of the squares on the sides of a quadrilateral is greater than the sum of the squares on its diagonals by four times the square on the straight line which joins the middle points of the diagonals

29. O is the middle point of a given straight line AB, and from O as centre, any circle is described if P be any point on its circumference, shew that the sum of the squares on AP, BP is constant.

30 Given the base of a triangle, and the sum of the squares on the sides forming the vertical angle, find the locus of the vertex

31 ABC is an isosceles triangle in which AB and AC are equal AB is produced beyond the base to D, so that BD is equal to AB. Shew that the square on CD is equal to the square on AB together with twice the square on BC

32 In a right angled triangle the sum of the squares on the straight lines drawn from the right angle to the points of trisection of the hypotenuse is equal to five times the square on the line between the points of trisection

33 Three times the sum of the squares on the sides of a triangle is equal to four times the sum of the squares on the medians

34 ABC is a triangle, and O the point of intersection of its medians shew that

$$AB^2 + BC^2 + CA^2 = 3(OA^2 + OB^2 + OC^2)$$

35 ABCD is a quadrilateral, and X the middle point of the straight line joining the bisections of the diagonals, with X as centre any circle is described, and P is any point upon this circle shew that $PA^2 + PB^2 + PC^2 + PD^2$ is constant, being equal to

$$XA^2 + XB^2 + XC^2 + XD^2 + 4XP^2$$

36 The squares on the diagonals of a trapezium are together equal to the sum of the squares on its two oblique sides, with twice the rectangle contained by its parallel sides

PROBLEMS

37 Construct a rectangle equal to the difference of two squares

38 Divide a given straight line into two parts so that the rectangle contained by them may be equal to the square described on a given straight line which is less than half the straight line to be divided

39 Given a square and one side of a rectangle which is equal to the square, find the other side

40 Produce a given straight line so that the rectangle contained by the whole line thus produced, and the part produced, may be equal to the square on half the line

41 Produce a given straight line so that the rectangle contained by the whole line thus produced and the given line shall be equal to a given square

42 Divide a straight line AB into two parts at C, such that the rectangle contained by BC and another line X may be equal to the square on AC

PART II.

BOOK III.

Book III. deals with the properties of Circles

DEFINITIONS

1. A circle is a plane figure bounded by one line, which is called the circumference, and is such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another: this point is called the centre of the circle.

2. A radius of a circle is a straight line drawn from the centre to the circumference

3. A diameter of a circle is a straight line drawn through the centre, and terminated both ways by the circumference.

4. A semicircle is the figure bounded by a diameter of a circle and the part of the circumference cut off by the diameter.

From these definitions we draw the following inferences:

(i) The distance of a point from the centre of a circle is less than the radius, if the point is within the circumference and the distance of a point from the centre is greater than the radius, if the point is without the circumference

(ii) A point is within a circle if its distance from the centre is less than the radius and a point is without a circle if its distance from the centre is greater than the radius

(iii) Circles of equal radius are equal in all respects; that is to say, their areas and circumferences are equal.

(iv) A circle is divided by any diameter into two parts which are equal in all respects

5 Circles which have the same centre are said to be concentric

6 An arc of a circle is any part of the circumference

7. A chord of a circle is the straight line which joins any two points on the circumference

From these definitions it may be seen that a chord of a circle, which does not pass through the centre, divides the circumference into two unequal arcs, of these, the greater is called the major arc, and the less the minor arc. Thus the major arc is *greater*, and the minor arc *less* than the semicircumference

The major and minor arcs, into which a circumference is divided by a chord, are said to be conjugate to one another.

8 Chords of a circle are said to be equidistant from the centre, when the perpendiculars drawn to them from the centre are equal

and one chord is said to be further from the centre than another, when the perpendicular drawn to it from the centre is greater than the perpendicular drawn to the other

9 A secant of a circle is a straight line of indefinite length, which cuts the circumference in two points.

10 A tangent to a circle is a straight line which meets the circumference, but being produced, does not cut it. Such a line is said to touch the circle at a point, and the point is called the point of contact

If a secant, which cuts a circle at the points P and Q, gradually changes its position in such a way that P remains fixed, the point Q will ultimately approach the fixed point P, until at length these points may be made to coincide. When the straight line PQ reaches this limiting position, it becomes the *tangent* to the circle at the point P.

Hence a tangent may be defined as a straight line which passes through *two coincident points* on the circumference.

11. Circles are said to touch one another when they meet, but do not cut one another

When each of the circles which meet is *outside the other*, they are said to touch one another *externally*, or to have *external contact* when one of the circles is *within the other*, they are said to touch one another *internally*, or to have *internal contact*

12 A segment of a circle is the figure bounded by a chord and one of the two arcs into which the chord divides the circumference.

The chord of a segment is sometimes called its *base*.

13 An angle in a segment is one formed by two straight lines drawn from any point in the arc of the segment to the extremities of its chord.

[It will be shewn in Proposition 21, that all angles in the same segment of a circle are equal]

14 An angle at the circumference of a circle is one formed by straight lines drawn from a point on the circumference to the extremities of an arc such an angle is said to stand upon the arc, which it subtends

15 Similar segments of circles are those which contain equal angles

16 A sector of a circle is a figure bounded by two radii and the arc intercepted between them

SYMBOLS AND ABBREVIATIONS

In addition to the symbols and abbreviations given on page 10, we shall use the following.

\bigcirc for circle, \bigcirc^c for circumference

PROPOSITION 1. PROBLEM.

To find the centre of a given circle

Let ABC be a given circle
it is required to find its centre.

In the given circle draw any chord AB,
and bisect AB at D. 1. 10.

From D draw DC at right angles to AB; 1. 11.
and produce DC to meet the \odot^{co} at E and C

Bisect EC at F. 1. 10.

Then shall F be the centre of the \odot ABC.

First, the centre of the circle must be in EC:
for if not, let the centre be at a point G without EC.

Join AG, DG, BG.

Then in the \triangle^s GDA, GDB,

Because { Constr.
 $DA = DB,$
 and GD is common;
 and $GA = GB$, for by supposition they are radii;
 \therefore the $\angle GDA =$ the $\angle GDB$; 1. 8.

• these angles, being adjacent, are rt angles.

But the $\angle CDB$ is a rt. angle; Constr.

• the $\angle GDB =$ the $\angle CDB$, Ax 11.

the part equal to the whole, which is impossible.

\therefore G is not the centre.

So it may be shewn that no point outside EC is the centre,
 \therefore the centre lies in EC.

• F, the middle point of the diameter EC, must be the
centre of the \odot ABC. Q E F

COROLLARY. The straight line which bisects a chord of
a circle at right angles passes through the centre.

[For Exercises, see page 156.]

PROPOSITION 2 THEOREM

If any two points are taken in the circumference of a circle, the chord which joins them falls within the circle.

Let ABC be a circle, and A and B any two points on its \circ^{ce} then shall the chord AB fall within the circle

Find D, the centre of the \circ ABC,
and in AB take any point E.
Join DA, DE, DB.

III 1

In the $\triangle DAB$, because $DA = DB$,
the $\angle DAB =$ the $\angle DBA$

III Def 1
1. 5

But the ext $\angle DEB$ is greater than the int opp. $\angle DAE$,

1 16

, also the $\angle DEB$ is greater than the $\angle DBE$,
in the $\triangle DEB$, the side DB, which is opposite the greater
angle, is greater than DE which is opposite the less
that is to say, DE is less than a radius of the circle,

1 19

E falls within the circle
So also any other point between A. and B may be shewn
to fall within the circle

AB falls within the circle

Q E D

DEFINITION. A part of a curved line is said to be concave to a point when, any chord being taken in it, all straight lines drawn from the given point to the intercepted arc are cut by the chord if, when any chord is taken, no straight line drawn from the given point to the intercepted arc is cut by the chord, the curve is said to be convex to that point

Proposition 2 proves that the whole circumference of a circle is concave to its centre.

PROPOSITION 3 THEOREM.

If a straight line drawn through the centre of a circle bisects a chord which does not pass through the centre, it shall cut it at right angles.

and, conversely, if it cut it at right angles, it shall bisect it.

Let ABC be a circle; and let CD be a st line drawn through the centre, and AB a chord which does not pass through the centre.

First.

Let CD bisect AB at F :

then shall CD cut AB at rt angles

Find E, the centre of the circle ,

III 1

and join EA, EB.

Then in the \triangle^s AFE, BFE,

Because { $\begin{array}{l} AF = BF, \\ \text{and FE is common;} \\ \text{and AE} = \text{BE, being radii of the circle,} \\ \therefore \text{the } \angle AFE = \text{the } \angle BFE, \end{array}$ *Hyp.*

I 8.

\therefore these angles, being adjacent, are rt. angles,

that is, DC cuts AB at rt angles

Q E D

Conversely. Let CD cut AB at rt angles :

then shall CD bisect AB at F.

As before, find E the centre, and join EA, EB.

In the \triangle EAB, because EA = EB,

III Def 1.

\therefore the \angle EAB = the \angle EBA

I 5

Then in the \triangle^s EFA, EFB,

Because { $\begin{array}{l} \text{the } \angle EAF = \text{the } \angle EBF, \\ \text{and the } \angle EFA = \text{the } \angle EFB, \text{ being rt angles,} \\ \text{and EF is common;} \end{array}$ *Proved.*

I 26.

$\therefore AF = BF.$

Q E D

[For Exercises, see page 156]

EXERCISES

ON PROPOSITION 1

1 If two circles intersect at the points A, B, shew that the line which joins their centres bisects their common chord AB at right angles

2 AB, AC are two equal chords of a circle, shew that the straight line which bisects the angle BAC passes through the centre.

3 Two chords of a circle are given in position and magnitude. find the centre of the circle

4. Describe a circle that shall pass through three given points, which are not in the same straight line

5 Find the locus of the centres of circles which pass through two given points

6 Describe a circle that shall pass through two given points, and have a given radius

ON PROPOSITION 2

7 A straight line cannot cut a circle in more than two points

ON PROPOSITION 3

8 Through a given point within a circle draw a chord which shall be bisected at that point

9 The parts of a straight line intercepted between the circumferences of two concentric circles are equal

10 The line joining the middle points of two parallel chords of a circle passes through the centre

11 Find the locus of the middle points of a system of parallel chords drawn in a circle

12 If two circles cut one another, any two parallel straight lines drawn through the points of intersection to cut the circles, are equal.

13 PQ and XY are two parallel chords in a circle shew that the points of intersection of PX, QY, and of PY, QX, lie on the straight line which passes through the middle points of the given chords

PROPOSITION 4. THEOREM

If in a circle two chords cut one another, which do not both pass through the centre, they cannot both be bisected at their point of intersection.

Let ABCD be a circle, and AC, BD two chords which intersect at E, but do not both pass through the centre
then AC and BD shall not be *both* bisected at E

CASE I. If *one* chord passes through the centre, it is a diameter, and the centre is its middle point;
∴ it cannot be bisected by the other chord, which by hypothesis does not pass through the centre.

CASE II. If neither chord passes through the centre, then, if possible, let E be the middle point of *both*;
that is, let $AE = EC$, and $BE = ED$.

Find F, the centre of the circle III. 1.
Join EF.

Then, because FE, which passes through the centre, bisects the chord AC,

∴ the $\angle FEC$ is a rt angle Hyp

III. 3

And because FE, which passes through the centre, bisects the chord BD,

∴ the $\angle FED$ is a rt. angle

∴ the $\angle FEC = \text{the } \angle FED$,

the whole equal to its part, which is impossible.

∴ AC and BD are not *both* bisected at E. Q E D.

[For Exercises, see page 158]

PROPOSITION 5 THEOREM

If two circles cut one another, they cannot have the same centre

Let the two \odot^s AGC, BFC cut one another at C
then they shall not have the same centre

For, if possible, let the two circles have the same centre,
and let it be called E

Join EC,

and from E draw any st line to meet the \odot^{ces} at F and G

Then, because E is the centre of the \odot AGC, *Hyp*

$$EG = EC$$

And because E is also the centre of the \odot BFC, *Hyp*

$$EF = EC$$

$$EG = EF,$$

the whole equal to its part, which is impossible
the two circles have not the same centre.

Q E D

EXERCISES

ON PROPOSITION 4

1. If a parallelogram can be inscribed in a circle, the point of intersection of its diagonals must be at the centre of the circle

2. Rectangles are the only parallelograms that can be inscribed in a circle

ON PROPOSITION 5

3 Two circles, which intersect at one point, must also intersect at another

PROPOSITION 6. THEOREM.

If two circles touch one another internally, they cannot have the same centre

Let the two \bigcirc^s ABC, DEC touch one another internally at C

then they shall not have the same centre.

For, if possible, let the two circles have the same centre, and let it be called F

Join FC,

and from F draw any st line to meet the \bigcirc^{cs} at E and B

Then, because F is the centre of the \bigcirc ABC, *Hyp*
 $FB = FC$

And because F is the centre of the \bigcirc DEC, *Hyp*.
 $FE = FC$

$$FB = FE,$$

the whole equal to its part, which is impossible.

. the two circles have not the same centre. Q E.D

NOTE From Propositions 5 and 6 it is seen that circles, whose circumferences have any point in common, cannot be concentric, unless they coincide entirely.

Conversely, the circumferences of concentric circles can have no point in common.

PROPOSITION 7. THEOREM

If from any point within a circle which is not the centre, straight lines are drawn to the circumference, the greatest is that which passes through the centre, and the least is that which, when produced backwards, passes through the centre:

and of all other such lines, that which is nearer to the greatest is always greater than one more remote.

also two equal straight lines, and only two, can be drawn from the given point to the circumference, one on each side of the diameter

Let ABCD be a circle, within which any point F is taken, which is not the centre let FA, FB, FC, FG be drawn to the \bigcirc^{ce} , of which FA passes through E the centre, and FB is nearer than FC to FA, and FC nearer than FG and let FD be the line which, when produced backwards, passes through the centre then of all these st lines

- (i) FA shall be the greatest,
- (ii) FD shall be the least,
- (iii) FB shall be greater than FC, and FC greater than FG,
- (iv) also two, and only two, equal st lines can be drawn from F to the \bigcirc^{ce}

Join EB, EC, EG.

- (i) Then in the $\triangle FEB$, the two sides FE, EB are together greater than the third side FB

1 20

But $EB = EA$, being radii of the circle,
 FE, EA are together greater than FB,
 that is, FA is greater than FB

Similarly FA may be shewn to be greater than any other st. line drawn from F to the \bigcirc^{ce} ;

\therefore FA is the greatest of all such lines.

(ii) In the $\triangle EFG$, the two sides EF, FG are together greater than EG, I. 20.

and $EG = ED$, being radii of the circle,

\therefore EF, FG are together greater than ED.

Take away the common part EF,

then FG is greater than FD.

Similarly any other st. line drawn from F to the \bigcirc^{ce} may be shewn to be greater than FD.

\therefore FD is the least of all such lines

(iii) In the \triangle^s BEF, CEF,

Because $\left\{ \begin{array}{l} BE = CE, \\ \text{and EF is common;} \end{array} \right.$ III. Def 1.

$\left\{ \begin{array}{l} \text{but the } \angle BEF \text{ is greater than the } \angle CEF, \\ \therefore FB \text{ is greater than FC} \end{array} \right.$ I. 24

Similarly it may be shewn that FC is greater than FG.

(iv) At E in FE make the $\angle FEH$ equal to the $\angle FEG$ I. 23.

Join FH.

Then in the \triangle^s GEF, HEF,

Because $\left\{ \begin{array}{l} GE = HE, \\ \text{and EF is common,} \end{array} \right.$ III. Def. 1

$\left\{ \begin{array}{l} \text{also the } \angle GEF = \text{the } \angle HEF, \\ \therefore FG = FH. \end{array} \right.$ Constn
I 4

And besides FH no other straight line can be drawn from F to the \bigcirc^{ce} equal to FG

For, if possible, let $FK = FG$.

Then, because $FH = FG$, Proved.

$\therefore FK = FH$,

that is, a line nearer to FA, the greatest, is equal to a line which is more remote; which is impossible Proved.

\therefore two, and only two, equal st lines can be drawn from F to the \bigcirc^{ce} . Q.E.D.

PROPOSITION 8 THEOREM

If from any point without a circle straight lines are drawn to the circumference, of those which fall on the concave circumference, the greatest is that which passes through the centre, and of others, that which is nearer to the greatest is always greater than one more remote

further, of those which fall on the convex circumference, the least is that which, when produced, passes through the centre, and of others that which is nearer to the least is always less than one more remote

lastly, from the given point there can be drawn to the circumference two, and only two, equal straight lines, one on each side of the shortest line

Let BGD be a circle of which C is the centre, and let A be any point outside the circle let ABD, AEH, AFG, be st lines drawn from A, of which AD passes through C, the centre, and AH is nearer than AG to AD

then of st lines drawn from A to the concave \bigcirc^{ce} ,

(i) AD shall be the greatest, and (ii) AH greater than AG

and of st lines drawn from A to the convex \bigcirc^{ce} ,

(iii) AB shall be the least, and (iv) AE less than AF

(v) Also two, and only two, equal st lines can be drawn from A to the \bigcirc^{ce}

Join CH, CG, CF, CE

(1) Then in the $\triangle ACH$, the two sides AC, CH are together greater than AH

but CH = CD, being radii of the circle,

AC, CD are together greater than AH

that is, AD is greater than AH

I 20

Similarly AD may be shewn to be greater than any other st line drawn from A to the concave \bigcirc^{ce} ,

AD is the greatest of all such lines

(ii) In the \triangle^s HCA, GCA,
 Because $\left\{ \begin{array}{l} HC = GC, \\ \text{and } CA \text{ is common;} \\ \text{but the } \angle HCA \text{ is greater than the } \angle GCA; \end{array} \right.$ III. Def. 1.
 $\therefore AH$ is greater than AG . I. 24.

(iii) In the \triangle AEC, the two sides AE, EC are together greater than AC. I. 20.

but $EC = BC$; III Def. 1.
 \therefore the remainder AE is greater than the remainder AB.

Similarly any other st line drawn from A to the convex O^{ca} may be shewn to be greater than AB,

$\therefore AB$ is the least of all such lines

(iv) In the $\triangle AFC$, because AE, EC are drawn from the extremities of the base to a point E within the triangle,

$\therefore AF, FC$ are together greater than AE, EC I. 21.

But $FC = EC$, III Def 1

\therefore the remainder AF is greater than the remainder AE.

(v) At C, in AC, make the $\angle ACM$ equal to the $\angle ACE$.
 Join AM.

Then in the two \triangle^s ECA, MCA,

Because $\left\{ \begin{array}{l} EC = MC, \\ \text{and } CA \text{ is common;} \\ \text{also the } \angle ECA = \text{the } \angle MCA; \end{array} \right.$ III. Def. 1
 $\therefore AE = AM$, I. 4. Constr

and besides AM, no st line can be drawn from A to the O^{ca} , equal to AE.

For, if possible, let $AK = AE$

then because $AM = AE$, Proved
 $\therefore AM = AK$,

that is, a line nearer to the shortest line is equal to a line which is more remote, which is impossible Proved

\therefore two, and only two, equal st. lines can be drawn from A to the O^{ca} . Q E D

Where are the limits of that part of the circumference which is concave to the point A?

Obs. Of the following proposition Euclid gave two distinct proofs, the first of which has the advantage of being *direct*.

PROPOSITION 9 THEOREM [FIRST PROOF]

If from a point within a circle more than two equal straight lines can be drawn to the circumference, that point is the centre of the circle.

Let ABC be a circle, and D a point within it, from which more than two equal st lines are drawn to the \bigcirc^e , namely DA, DB, DC.

then D shall be the centre of the circle

Join AB, BC
and bisect AB, BC at E and F respectively I 10
Join DE, DF

Then in the \triangle^s DEA, DEB,

Because $\begin{cases} EA = EB, \\ \text{and DE is common,} \\ \text{and DA} = \text{DB,} \end{cases}$ Constr

∴ the \angle DEA = the \angle DEB, Hyp I 8

∴ these angles, being adjacent, are rt angles

Hence ED, which bisects the chord AB at rt angles, must pass through the centre III 1 Cor

Similarly it may be shewn that FD passes through the centre

∴ D, which is the only point common to ED and FD, must be the centre
Q.E.D.

PROPOSITION 9. THEOREM. [SECOND PROOF]

If from a point within a circle more than two equal straight lines can be drawn to the circumference, that point is the centre of the circle

Let ABC be a circle, and D a point within it, from which more than two equal st lines are drawn to the \bigcirc^c , namely DA, DB, DC.

then D shall be the centre of the circle.

For, if not, suppose E to be the centre

Join DE, and produce it to meet the \bigcirc^c at F, G

Then because D is a point within the circle, not the centre, and because DF passes through the centre E;

\therefore DA, which is nearer to DF, is greater than DB, which is more remote. III 7

but this is impossible, since by hypothesis, DA, DB, are equal.

\therefore E is not the centre of the circle

*And wherever we suppose the centre E to be, otherwise than at D, two at least of the st lines DA, DB, DC may be shewn to be unequal, which is contrary to hypothesis.

\therefore D is the centre of the \bigcirc ABC.

Q E D

* NOTE. For example, if the centre E were supposed to be within the angle BDC, then DB would be greater than DA; if within the angle ADB, then DB would be greater than DC; if on one of the three straight lines, as DB, then DB would be greater than both DA and DC.

Obs Two proofs of Proposition 10, both indirect, were given by Euclid.

PROPOSITION 10 THEOREM [FIRST PROOF]

One circle cannot cut another at more than two points

If possible, let DABC, EABC be two circles, cutting one another at more than two points, namely at A, B, C,

Join AB, BC

Draw FH, bisecting AB at rt angles, I 10, 11
and draw GH bisecting BC at rt angles

Then because AB is a chord of *both* circles, and FH bisects it at rt angles,

the centre of both circles lies in FH III 1 Cor

Again, because BC is a chord of both circles, and GH bisects it at right angles,

the centre of both circles lies in GH III 1 Cor.

Hence H, the only point common to FH and GH, is the centre of both circles,

which is impossible, for circles which cut one another cannot have a common centre III 5

one circle cannot cut another at more than two points

Q.E.D.

COROLLARIES (i) *Two circles cannot meet in three points without coinciding entirely*

(ii) *Two circles cannot have a common arc without coinciding entirely*

(iii) *Only one circle can be described through three points, which are not in the same straight line.*

PROPOSITION 10. THEOREM [SECOND PROOF.]

One circle cannot cut another at more than two points

If possible, let DABC, EABC be two circles, cutting one another at more than two points, namely at A, B, C.

Find H, the centre of the \odot DABC, III 1.
and join HA, HB, HC.

Then since H is the centre of the \odot DABC,
 \therefore HA, HB, HC are all equal III. Def. 1.

And because H is a point within the \odot EABC, from which more than two equal st. lines, namely HA, HB, HC are drawn to the \odot^e ,

H is the centre of the \odot EABC III. 9.

that is to say, the two circles have a common centre H,
but this is impossible, since they cut one another. III. 5

Therefore one circle cannot cut another in more than two points. Q.E.D.

NOTE This proof is imperfect, because it assumes that the centre of the circle DABC must fall within the circle EABC, whereas it may be conceived to fall either without the circle EABC, or on its circumference. Hence to make the proof complete, two additional cases are required.

PROPOSITION 11 THEOREM

If two circles touch one another internally, the straight line which joins their centres, being produced, shall pass through the point of contact

Let ABC and ADE be two circles which touch one another internally at A, let F be the centre of the \odot ABC, and G the centre of the \odot ADE:

then shall FG produced pass through A

If not, let it pass otherwise, as FGEH

Join FA, GA

Then in the \triangle FGA, the two sides FG, GA are together greater than FA

I 20

but FA = FH, being radii of the \odot ABC

Hyp

FG, GA are together greater than FH

Take away the common part FG,

then GA is greater than GH

But GA = GE, being radii of the \odot ADE

Hyp

\therefore GE is greater than GH,

the part greater than the whole, which is impossible

FG, when produced, must pass through A

Q E D

EXERCISES

1 If the distance between the centres of two circles is equal to the difference of their radii, then the circles must meet in one point, but in no other, that is, they must touch one another

2 If two circles whose centres are A and B touch one another internally, and a straight line be drawn through their point of contact, cutting the circumferences at P and Q, shew that the radii AP and BQ are parallel

PROPOSITION 12. THEOREM

If two circles touch one another externally, the straight line which joins their centres shall pass through the point of contact.

Let ABC and ADE be two circles which touch one another externally at A, let F be the centre of the \odot ABC, and G the centre of the \odot ADE.

then shall FG pass through A.

If not, let FG pass otherwise, as FHKG.

Join FA, GA

Then in the \triangle FAG, the two sides FA, GA are together greater than FG

but FA = FH, being radii of the \odot ABC;

and GA = GK, being radii of the \odot ADE,

FH and GK are together greater than FG;

which is impossible

FG must pass through A.

Q E D

EXERCISES

1 Find the locus of the centres of all circles which touch a given circle at a given point

2 Find the locus of the centres of all circles of given radius, which touch a given circle.

3 If the distance between the centres of two circles is equal to the sum of their radii, then the circles meet in one point, but in no other, that is, they touch one another.

4 If two circles whose centres are A and B touch one another externally, and a straight line be drawn through their point of contact cutting the circumferences at P and Q, shew that the radii AP and BQ are parallel.

PROPOSITION 13 THEOREM

Two circles cannot touch one another at more than one point, whether internally or externally.

If possible, let ABC, EDF be two circles which touch one another at more than one point, namely at B and D.

Join BD,

and draw GF, bisecting BD at rt angles 10, 11

Then, whether the circles touch one another internally, as in Fig 1, or externally as in Fig 2,

because B and D are on the \odot^{ces} of both circles,

\therefore BD is a chord of both circles

\therefore the centres of both circles lie in GF, which bisects BD at rt angles III 1. Cor.

Hence GF which joins the centres must pass through a point of contact, III 11, and 12

which is impossible, since B and D are without GF.

\therefore two circles cannot touch one another at more than one point

Q E D.

NOTE It must be observed that the proof here given applies, by virtue of Propositions 11 and 12, to *both* the above figures we have therefore omitted the separate discussion of Fig 2, which finds a place in most editions based on Simson's text.

EXERCISES ON PROPOSITIONS 1—13.

1. Describe a circle to pass through two given points and have its centre on a given straight line. When is this impossible?
2. All circles which pass through a fixed point, and have their centres on a given straight line, pass also through a second fixed point.
3. Describe a circle of given radius to touch a given circle at a given point. How many solutions will there be? When will there be only one solution?
4. From a given point as centre describe a circle to touch a given circle. How many solutions will there be?
5. Describe a circle to pass through a given point, and touch a given circle at a given point [See Ex. 1, p 169 and Ex 5, p. 156.] When is this impossible?
6. Describe a circle of given radius to touch two given circles [See Ex 2, p 169] How many solutions will there be?
7. Two parallel chords of a circle are six inches and eight inches in length respectively, and the perpendicular distance between them is one inch find the radius
8. If two circles touch one another externally, the straight lines, which join the extremities of parallel diameters towards opposite parts, must pass through the point of contact.
9. Find the greatest and least straight lines which have one extremity on each of two given circles, which do not intersect.
10. In any segment of a circle, of all straight lines drawn at right angles to the chord and intercepted between the chord and the arc, the greatest is that which passes through the middle point of the chord, and of others that which is nearer the greatest is greater than one more remote.
11. If from any point on the circumference of a circle straight lines be drawn to the circumference, the greatest is that which passes through the centre, and of others, that which is nearer to the greatest is greater than one more remote; and from this point there can be drawn to the circumference two, and only two, equal straight lines.

PROPOSITION 14 THEOREM

Equal chords in a circle are equidistant from the centre and, conversely, chords which are equidistant from the centre are equal.

Let ABC be a circle, and let AB and CD be chords, of which the perp distances from the centre are EF and EG

First,

Let $AB = CD$

then shall AB and CD be equidistant from the centre E

Join EA, EC

Then, because EF, which passes through the centre, is perp to the chord AB,

Hyp

EF bisects AB,

III 3

that is, AB is double of FA

For a similar reason, CD is double of GC

But $AB = CD$,

Hyp

$FA = GC$

Now $EA = EC$, being radii of the circle,
the sq on EA = the sq on EC

But the sq on EA = the sqq on EF, FA,
for the $\angle EFA$ is a rt angle

I. 47

And the sq on EC = the sqq on EG, GC;
for the $\angle EGC$ is a rt angle

the sqq on EF, FA = the sqq on EG, GC

Now of these, the sq on FA = the sq on GC, for $FA = GC$
the sq on EF = the sq on EG,

$EF = EG$,

that is, the chords AB, CD are equidistant from the centre

Q.E.D.

Conversely. Let AB and CD be equidistant from the centre E;

that is, let $EF = EG$:

then shall $AB = CD$.

For, the same construction being made, it may be shewn as before that AB is double of FA, and CD double of GC;

and that the sqq on EF, $FA =$ the sqq on EG, GC

Now of these, the sq on EF = the sq on EG,

for $EF = EG$:

Hyp.

\therefore the sq on FA = the square on GC ;

$\therefore FA = GC$;

and doubles of these equals are equal ;

that is, $AB = CD$.

Q E D.

EXERCISES.

1. Find the locus of the middle points of equal chords of a circle.
- ✓ 2. If two chords of a circle cut one another, and make equal angles with the straight line which joins their point of intersection to the centre, they are equal.
3. If two equal chords of a circle intersect, shew that the segments of the one are equal respectively to the segments of the other.
4. In a given circle draw a chord which shall be equal to one given straight line (not greater than the diameter) and parallel to another.
5. PQ is a fixed chord in a circle, and AB is any diameter: shew that the difference of the perpendiculars let fall from A and B on PQ is constant, that is, the same for all positions of AB.

PROPOSITION 15 THEOREM.

*The diameter is the greatest chord in a circle ,
and of others, that which is nearer to the centre is greater
than one more remote
conversely, the greater chord is nearer to the centre than
the less.*

Let ABCD be a circle, of which AD is a diameter, and E the centre , and let BC and FG be any two chords, whose perp distances from the centre are EH and EK .

then (i) AD shall be greater than BC

(ii) if EH is less than EK, BC shall be greater than FG

(iii) if BC is greater than FG, EH shall be less than EK.

(1) Join EB, EC

Then in the $\triangle BEC$, the two sides BE, EC are together greater than BC ,

but BE = AE,

I 20

and EC = ED ,

III Def. 1

• AE and ED together are greater than BC ,

that is, AD is greater than BC

Similarly AD may be shewn to be greater than any other chord, not a diameter

(ii)

Let EH be less than EK;

then BC shall be greater than FG

Join EF

Since EH, passing through the centre, is perp to the chord BC,

EH bisects BC ,

III 3.

that is, BC is double of HB

For a similar reason FG is double of KF

Now $EB = EF$,

III. *Def.* 1.

\therefore the sq on EB = the sq on EF

But the sq on EB = the sqq on EH, HB;

for the \angle EHB is a rt angle,

I. 47.

also the sq on EF = the sqq on EK, KF,

for the \angle EKF is a rt angle.

\therefore the sqq on EH, HB = the sqq. on EK, KF

But the sq on EH is less than the sq. on EK,

for EH is less than EK,

Hyp

\therefore the sq. on HB is greater than the sq on KF,

HB is greater than KF:

hence BC is greater than FG.

(iii) Let BC be greater than FG,
then EH shall be less than EK

For since BC is greater than FG,

Hyp

HB is greater than KF:

the sq on HB is greater than the sq on KF.

But the sqq on EH, HB = the sqq on EK, KF *Proved*

\therefore the sq on EH is less than the sq on EK,

\therefore EH is less than EK.

Q.E.D

EXERCISES

1. Through a given point within a circle draw the least possible chord.

2 AB is a fixed chord of a circle, and XY any other chord having its middle point Z on AB what is the greatest, and what the least length that XY may have?

Shew that XY increases, as Z approaches the middle point of AB.

3 In a given circle draw a chord of given length, having its middle point on a given chord,

When is this problem impossible?

Obs Of the following proofs of Proposition 16, the second (by *reductio ad absurdum*) is that given by Euclid, but the first is to be preferred, as it is *direct*, and not less simple than the other

PROPOSITION 16 THEOREM [ALTERNATIVE PROOF]

The straight line drawn at right angles to a diameter of a circle at one of its extremities is a tangent to the circle and every other straight line drawn through this point cuts the circle

Let AKB be a circle, of which E is the centre, and AB a diameter, and through B let the st. line CBD be drawn at rt angles to AB

then (i) CBD shall be a tangent to the circle,

(ii) any other st line through B, as BF, shall cut the circle

(1) In CD take any point G, and join EG

Then, in the $\triangle EBG$, the $\angle EBG$ is a rt angle, *Hyp*

the $\angle EGB$ is less than a rt angle, *I 17*

the $\angle EBG$ is greater than the $\angle EGB$,

EG is greater than EB *I 19*

that is, EG is greater than a radius of the circle,

the point G is without the circle

Similarly any other point in CD, except B, may be shewn to be outside the circle

hence CD meets the circle at B, but being produced, does not cut it;

that is, CD is a tangent to the circle *III Def 10*

(ii) Draw EH perp to BF. I. 12.

Then in the $\triangle EHB$, because the $\angle EHB$ is a rt angle,
the $\angle EBH$ is less than a rt angle, I. 17

EB is greater than EH, I. 19.

that is, EH is less than a radius of the circle

H, a point in BF, is within the circle,

BF must cut the circle. Q E. D.

PROPOSITION 16. THEOREM. [EUCLID'S PROOF]

The straight line drawn at right angles to a diameter of a circle at one of its extremities, is a tangent to the circle and no other straight line can be drawn through this point so as not to cut the circle

Let ABC be a circle, of which D is the centre, and AB a diameter, let AE be drawn at rt angles to BA, at its extremity A.

(1) then shall AE be a tangent to the circle

For, if not, let AE cut the circle at C

Join DC

Then in the $\triangle DAC$, because $DA = DC$, III. Def 1.

\therefore the $\angle DAC =$ the $\angle DCA$.

But the $\angle DAC$ is a rt angle; Hyp

the $\angle DCA$ is a rt angle,

that is, two angles of the $\triangle DAC$ are together equal to two rt angles, which is impossible I. 17

Hence AE meets the circle at A, but being produced, does not cut it,

that is, AE is a tangent to the circle III Def 10

(11) Also through A no other straight line but AE can be drawn so as not to cut the circle

For, if possible, let AF be another st line drawn through A so as not to cut the circle

From D draw DG perp to AF, I 12.
and let DG meet the \bigcirc^{ce} at H

Then in the $\triangle DAG$, because the $\angle DGA$ is a rt angle,
 . the $\angle DAG$ is less than a rt angle, I 17
 . DA is greater than DG I 19
 But $DA = DH$, III Def 1

DH is greater than DG,

the part greater than the whole, which is impossible
 no st line can be drawn from the point A, so as not to cut the circle, except AE

COROLLARIES (1) *A tangent touches a circle at one point only*

(11) *There can be but one tangent to a circle at a given point.*

But the $\angle FDE$ is a rt. angle,

Constr.

the $\angle ABE$ is a rt. angle,

hence AB, being drawn at rt angles to a diameter at one of its extremities, is a tangent to the $\odot BCD$ III 16

Similarly it may be shewn that AC is a tangent Q E F

COROLLARY *If two tangents are drawn to a circle from an external point, then (i) they are equal, (ii) they subtend equal angles at the centre, (iii) they make equal angles with the straight line which joins the given point to the centre*

For, in the above figure,

Since ED is perp to FG, a chord of the $\odot FAG$,

$$DF = DG$$

III 3.

Then in the $\triangle^s DEF, DEG$,

Because $\left\{ \begin{array}{l} DE \text{ is common to both,} \\ \text{and } EF = EG, \\ \text{and } DF = DG, \end{array} \right.$

III Def. 1
Proved

the $\angle DEF = \text{the } \angle DEG$ I 8

Again in the $\triangle^s AEB, AEC$,

Because $\left\{ \begin{array}{l} AE \text{ is common to both,} \\ \text{and } EB = EC, \\ \text{and the } \angle AEB = \text{the } \angle AEC, \end{array} \right.$

Proved

$$AB = AC.$$

I 4

and the $\angle EAB = \text{the } \angle EAC$ Q.E.D.

Q.E.D.

NOTE. If the given point A is within the circle, no solution is possible

Hence we see that this problem admits of *two* solutions, *one* solution, or *no* solution, according as the given point A is *without*, *on*, or *within* the circumference of a circle

For a simpler method of drawing a tangent to a circle from a given point, see page 202

PROPOSITION 18 THEOREM

The straight line drawn from the centre of a circle to the point of contact of a tangent is perpendicular to the tangent

Let ABC be a circle, of which F is the centre,
and let the st line DE touch the circle at C.
then shall FC be perp to DE

For, if not, suppose FG to be perp to DE, I. 12.
and let it meet the \bigcirc^{ce} at B

Then in the $\triangle FCG$, because the $\angle FGC$ is a rt angle, Hyp
the $\angle FCG$ is less than a rt angle: I. 17.

the $\angle FGC$ is greater than the $\angle FCG$,
FC is greater than FG I. 19

but $FC = FB$;

FB is greater than FG,

the part greater than the whole, which is impossible

FC cannot be otherwise than perp to DE

that is, FC is perp to DE Q E D

EXERCISES

1 Draw a tangent to a circle (i) parallel to, (ii) at right angles to a given straight line

2 Tangents drawn to a circle from the extremities of a diameter are parallel

3 Circles which touch one another internally or externally have a common tangent at their point of contact

4 In two concentric circles any chord of the outer circle which touches the inner, is bisected at the point of contact

5 In two concentric circles, all chords of the outer circle which touch the inner, are equal

PROPOSITION 19 THEOREM

The straight line drawn perpendicular to a tangent to a circle from the point of contact passes through the centre

Let ABC be a circle, and DE a tangent to it at the point C, and let CA be drawn perp to DE

then shall CA pass through the centre

For if not, suppose the centre to be outside CA, as at F

Join CF

Then because DE is a tangent to the circle, and FC is drawn from the centre F to the point of contact,

the $\angle FCE$ is a rt. angle

III 18

But the $\angle ACE$ is a rt. angle,

Hyp

the $\angle FCE = \text{the } \angle ACE$,

the part equal to the whole, which is impossible

the centre cannot be otherwise than in CA,

that is, CA passes through the centre

Q E D

EXERCISES ON THE TANGENT

PROPOSITIONS 16, 17, 18, 19

1 The centre of any circle which touches two intersecting straight lines must lie on the bisector of the angle between them

2 AB and AC are two tangents to a circle whose centre is O, shew that AO bisects the chord of contact BC at right angles

3 If two circles are concentric all tangents drawn from points on the circumference of the outer to the inner circle are equal

4 The diameter of a circle bisects all chords which are parallel to the tangent at either extremity

5 Find the locus of the centres of all circles which touch a given straight line at a given point

6 Find the locus of the centres of all circles which touch each of two parallel straight lines.

7 Find the locus of the centres of all circles which touch each of two intersecting straight lines of unlimited length

8 Describe a circle of given radius to touch two given straight lines

9 Through a given point, within or without a circle, draw a chord equal to a given straight line

In order that the problem may be possible, between what limits must the given line lie, when the given point is (1) without the circle, (2) within it?

10 Two parallel tangents to a circle intercept on any third tangent a segment which subtends a right angle at the centre

11 In any quadrilateral circumscribed about a circle, the sum of one pair of opposite sides is equal to the sum of the other pair

12 Any parallelogram which can be circumscribed about a circle, must be equilateral

13 If a quadrilateral be described about a circle, the angles subtended at the centre by any two opposite sides are together equal to two right angles

14 AB is any chord of a circle, AC the diameter through A, and AD the perpendicular on the tangent at B shew that AB bisects the angle DAC

15 Find the locus of the extremities of tangents of fixed length drawn to a given circle

16 In the diameter of a circle produced, determine a point such that the tangent drawn from it shall be of given length

17 In the diameter of a circle produced, determine a point such that the two tangents drawn from it may contain a given angle

18 Describe a circle that shall pass through a given point, and touch a given straight line at a given point. [See page 183. Ex 5]

19 Describe a circle of given radius, having its centre on a given straight line, and touching another given straight line

20. Describe a circle that shall have a given radius, and touch a given circle and a given straight line How many such circles can be drawn?

PROPOSITION 20 THEOREM

The angle at the centre of a circle is double of an angle at the circumference, standing on the same arc

Fig 1

Fig 2

Let ABC be a circle, of which E is the centre, and let BEC be an angle at the centre, and BAC an angle at the O^e , standing on the same arc BC

then shall the \angle BEC be double of the \angle BAC

Join AE, and produce it to F

CASE I When the centre E is within the angle BAC

Then in the \triangle EAB, because EA = EB,

the \angle EAB = the \angle EBA, I 5

the sum of the \angle^s EAB, EBA = twice the \angle EAB

But the ext \angle BEF = the sum of the \angle^s EAB, EBA, I 32

the \angle BEF = twice the \angle EAB

Similarly the \angle FEC = twice the \angle EAC

the sum of the \angle^s BEF, FEC = twice the sum of the \angle^s EAB, EAC,
that is, the \angle BEC = twice the \angle BAC.

CASE II When the centre E is without the \angle BAC

As before, it may be shewn that the \angle FEB = twice the \angle FAB,

also the \angle FEC = twice the \angle FAC,

the difference of the \angle^s FEC, FEB = twice the difference of the \angle^s FAC, FAB

that is, the \angle BEC = twice the \angle BAC

NOTE If the arc BFC, on which the angles stand, is greater than a semi-circumference, it is clear that the angle BEC at the centre will be *reflex* but it may still be shewn as, in Case I, that the reflex \angle BEC is double of the \angle BAC at the O^{ce} , standing on the same arc BFC

PROPOSITION 21 THEOREM

Angles in the same segment of a circle are equal

Let ABCD be a circle, and let BAD, BED be angles in the same segment BAED

then shall the \angle BAD = the \angle BED

Find F, the centre of the circle III 1

CASE I When the segment BAED is greater than a semicircle

Join BF, DF

Then the \angle BFD at the centre = twice the \angle BAD at the O^{ce} , standing on the same arc BD III 20

and similarly the \angle BFD = twice the \angle BED III 20

. the \angle BAD = the \angle BED

CASE II When the segment BAED is not greater than a semicircle

Join AF, and produce it to meet the \bigcirc^{cc} at C
Join EC

Then since AEDC is a semicircle,
the segment BAEC is greater than a semicircle
the $\angle BAC = \text{the } \angle BEC$, in this segment *Case 1*
Similarly the segment CAED is greater than a semicircle,
the $\angle CAD = \text{the } \angle CED$, in this segment
the sum of the $\angle^s BAC, CAD = \text{the sum of the } \angle^s BEC, CED$
that is, the $\angle BAD = \text{the } \angle BED$ Q E D

EXERCISES

- 1 P is any point on the arc of a segment of which AB is the chord. Shew that the sum of the angles PAB, PBA is constant
- 2 PQ and RS are two chords of a circle intersecting at X. prove that the triangles PXS, RXQ are equiangular
- 3 Two circles intersect at A and B, and through A any straight line PAQ is drawn terminated by the circumferences. show that PQ subtends a constant angle at B
- 4 Two circles intersect at A and B, and through A any two straight lines PAQ, XAY are drawn terminated by the circumferences. shew that the arcs PX, QY subtend equal angles at B
- 5 P is any point on the arc of a segment whose chord is AB and the angles PAB, PBA are bisected by straight lines which intersect at O. Find the locus of the point O

NOTE If the extension of Proposition 20, given in the note on page 185, is adopted, a separate treatment of the second case of the present proposition is unnecessary

For, as in Case I,
 the reflex $\angle BFD =$ twice the $\angle BAD$, III 20
 also the reflex $\angle BFD =$ twice the $\angle BED$,
 \therefore the $\angle BAD =$ the $\angle BED$

The converse of Proposition 21 is very important For the construction used in its proof, viz *To describe a circle about a given triangle*, the student is referred to Book IV Proposition 5 [Or see Theorems and Examples on Book I Page 103, No 1]

CONVERSE OF PROPOSITION 21

Equal angles standing on the same base, and on the same side of it, have their vertices on an arc of a circle, of which the given base is the chord

Let $\angle BAC, \angle BDC$ be two equal angles standing on the same base BC

then shall the vertices A and D lie upon a segment of a circle having BC as its chord

Describe a circle about the $\triangle BAC$ IV 5
 then this circle shall pass through D .

For, if not, it must cut BD , or BD produced, at some other point E

Join EC

Then the $\angle BAC =$ the $\angle BEC$, in the same segment III 21

but the $\angle BAC =$ the $\angle BDC$, by hypothesis,

\therefore the $\angle BEC =$ the $\angle BDC$,

that is, an ext angle of a triangle = an int opp angle,
 which is impossible I 16

the circle which passes through B, A, C , cannot pass otherwise than through D

That is, the vertices A and D are on an arc of a circle of which the chord is BC Q E.D.

The following corollary is important

All triangles drawn on the same base, and with equal vertical angles, have their vertices on an arc of a circle, of which the given base is the chord

On, The locus of the vertices of triangles drawn on the same base with equal vertical angles is an arc of a circle

PROPOSITION 22 THEOREM

The opposite angles of any quadrilateral inscribed in a circle are together equal to two right angles

Let ABCD be a quadrilateral inscribed in the $\odot ABC$,
 then shall, (1) the \angle^s ADC, ABC together = two rt angles,
 (2) the \angle^s BAD, BCD together = two rt angles

Join AC, BD

Then the $\angle ADB =$ the $\angle ACB$, in the segment ADCB, III. 21.
 also the $\angle CDB =$ the $\angle CAB$, in the segment CDAB

the $\angle ADC =$ the sum of the \angle^s ACB, CAB

To each of these equals add the $\angle ABC$

then the two \angle^s ADC, ABC together = the three \angle^s ACB, CAB, ABC

But the \angle^s ACB, CAB, ABC, being the angles of a triangle, together = two rt angles I 32

the \angle^s ADC, ABC together = two rt angles

Similarly it may be shewn that

the \angle^s BAD, BCD together = two rt angles

Q E D

EXERCISES

1 If a circle can be described about a parallelogram, the parallelogram must be rectangular

2 ABC is an isosceles triangle, and XY is drawn parallel to the base BC shew that the four points B, C, X, Y lie on a circle

3 If one side of a quadrilateral inscribed in a circle is produced, the exterior angle is equal to the opposite interior angle of the quadrilateral

PROPOSITION 22 [Alternative Proof]

Let ABCD be a quadrilateral inscribed in the $\odot ABC$
 then shall the \angle^s ADC, ABC together = two rt angles

Join FA, FC

Then the $\angle AFC$ at the centre = twice the
 $\angle ADC$ at the O^ce , standing on the same arc
 ABC III 20

Also the reflex angle AFC at the centre
 = twice the $\angle ABC$ at the O^ce , standing on the
 same arc ADC III 20

Hence the \angle^s ADC, ABC are together half
 the sum of the $\angle AFC$ and the reflex angle AFC,
 but these make up four rt angles I 15 Cor 2
 the \angle^s ADC, ABC together = two rt. angles Q E D

✓ DEFINITION Four or more points through which a circle
 may be described are said to be concyclic

CONVERSE OF PROPOSITION 22

If a pair of opposite angles of a quadrilateral are together equal to
 two right angles, its vertices are concyclic

Let ABCD be a quadrilateral, in which the opposite angles at
 B and D together = two rt. angles,

then shall the four points A, B, C, D be
 concyclic

Through the three points A, B, C describe
 a circle IV 5

then this circle must pass through D

For, if not, it will cut AD, or AD produced,
 at some other point E

Join EC

Then since the quadrilateral ABCE is inscribed in a circle,

the \angle^s ABC, AEC together = two rt angles III 22

But the \angle^s ABC, ADC together = two rt angles, Hyp

hence the \angle^s ABC, AEC = the \angle^s ABC, ADC

Take from these equals the $\angle ABC$

then the $\angle AEC$ = the $\angle ADC$,

that is, an ext angle of a triangle = an int opp angle,
 which is impossible I 16

the circle which passes through A, B, C cannot pass otherwise
 than through D

that is the four vertices A, B, C, D are concyclic Q E D

DEFINITION Similar segments of circles are those which contain equal angles

PROPOSITION 23 THEOREM

On the same chord and on the same side of it, there cannot be two similar segments of circles, not coinciding with one another

If possible, on the same chord AB, and on the same side of it, let there be two similar segments of circles ACB, ADB, not coinciding with one another

Then since the arcs ADB, ACB intersect at A and B,
they cannot cut one another again, III 10
one segment falls within the other

In the outer arc take any point D,
join AD, cutting the inner arc at C
join CB, DB

Then because the segments are similar,
the $\angle ACB = \angle ADB$, III Def
that is, an ext angle of a triangle = an int opp angle,
which is impossible I 16

Hence the two similar segments ACB, ADB, on the same chord AB and on the same side of it, must coincide

Q E D

EXERCISES ON PROPOSITION 22

1 The straight lines which bisect any angle of a quadrilateral figure inscribed in a circle and the opposite exterior angle, meet on the circumference.

2 A triangle is inscribed in a circle shew that the sum of the angles in the three segments exterior to the triangle is equal to four right angles

3 Divide a circle into two segments, so that the angle contained by the one shall be double of the angle contained by the other

PROPOSITION 24 THEOREM

Similar segments of circles on equal chords are equal to one another

Let AEB and CFD be similar segments on equal chords AB, CD

then shall the segment ABE = the segment CDF

For if the segment ABE be applied to the segment CDF, so that A falls on C, and AB falls along CD,

then since $AB = CD$,

. B must coincide with D

the segment AEB must coincide with the segment CFD, for if not, on the same chord and on the same side of it there would be two similar segments of circles, not coinciding with one another. which is impossible III. 23

the segment AEB = the segment CFD Q E D

EXERCISES

1 Of two segments standing on the same chord, the greater segment contains the smaller angle

2 A segment of a circle stands on a chord AB, and P is any point on the same side of AB as the segment shew that the angle APB is greater or less than the angle in the segment, according as P is within or without the segment

3 P, Q, R are the middle points of the sides of a triangle, and X is the foot of the perpendicular let fall from one vertex on the opposite side. shew that the four points P, Q, R, X are concyclic
[See page 96, Ex 2. also page 100, Ex 2]

4 Use the preceding exercise to shew that the middle points of the sides of a triangle and the feet of the perpendiculars let fall from the vertices on the opposite sides, are concyclic

PROPOSITION 25 PROBLEM*

An arc of a circle being given, to describe the whole circumference of which the given arc is a part

Let ABC be an arc of a circle
it is required to describe the whole \bigcirc^e of which the arc ABC is a part

In the given arc take any three points A, B, C

Join AB, BC

Draw DF bisecting AB at rt angles, I 10 II
and draw EF bisecting BC at rt angles.

Then because DF bisects the chord AB at rt angles,
the centre of the circle lies in DF III 1 Cor

Again, because EF bisects the chord BC at rt angles,
the centre of the circle lies in EF III 1 Cor
the centre of the circle is F, the only point common to DF, EF

Hence the \bigcirc^e of a circle described from centre F, with radius FA, is that of which the given arc is a part Q.E.D.

* NOTE Euclid gave this proposition a somewhat different form, as follows

A segment of a circle being given, to describe the circle of which it is a segment

Let ABC be the given segment standing on the chord AC

Draw DB, bisecting AC at rt angles I 10

Join AB

At A, in BA, make the $\angle BAE$ equal to the $\angle ABD$ I 23

Let AE meet BD, or BD produced, at E
Then E shall be the centre of the required circle

[Join EC, and prove (i) $EA = EC$, I 4

(ii) $EA = EB$ I 6]

PROPOSITION 26 THEOREM

In equal circles the arcs which subtend equal angles, whether at the centres or at the circumferences, shall be equal

Let ABC, DEF be equal circles and let the $\angle^s BGC, EHF$, at the centres be equal, and consequently the $\angle^s BAC, EDF$ at the \bigcirc^{cs} equal III 20

then shall the arc $BKC =$ the arc ELF

Join BC, EF .

Then because the $\bigcirc^s ABC, DEF$ are equal,
 . then radii are equal

Hence in the $\triangle^s BGC, EHF$,

Because $\left\{ \begin{array}{l} BG = EH, \\ \text{and } GC = HF, \\ \text{and the } \angle BGC = \text{the } \angle EHF, \\ BC = EF. \end{array} \right. \quad \begin{array}{l} \text{Hyp} \\ I\ 4 \end{array}$

Again, because the $\angle BAC =$ the $\angle EDF$, Hyp.
 the segment BAC is similar to the segment EDF ,
III Def 15

and they are on equal chords BC, EF ,
 . the segment $BAC =$ the segment EDF III 24

But the whole $\bigcirc ABC =$ the whole $\bigcirc DEF$,
 the remaining segment $BKC =$ the remaining segment ELF
 the arc $BKC =$ the arc ELF

Q E D

PROPOSITION 27 THEOREM

In equal circles the angles, whether at the centres or the circumferences, which stand on equal arcs, shall be equal

Let ABC , DEF be equal circles,
and let the arc $BC =$ the arc EF
then shall the $\angle BGC =$ the $\angle EHF$, at the centres,
and also the $\angle BAC =$ the $\angle EDF$, at the O^cs

If the \angle^s BGC , EHF are not equal, one must be the greater

If possible, let the $\angle BGC$ be the greater

At G , in BG , make the $\angle BGK$ equal to the $\angle EHF$ I 23

Then because in the equal O^s ABC , DEF ,

the $\angle BGK =$ the $\angle EHF$, at the centres,

the arc $BK =$ the arc EF

Constr

III 26

But the arc $BC =$ the arc EF ,

the arc $BK =$ the arc EF , BC

Hyp

a part equal to the whole, which is impossible

the $\angle BGC$ is not unequal to the $\angle EHF$,

that is, the $\angle BGC =$ the $\angle EHF$

And since the $\angle BAC$ at the O^c is half the $\angle BGC$ at the centre,

III 20

and likewise the $\angle EDF$ is half the $\angle EHF$,

the $\angle BAC =$ the $\angle EDF$

Q E D

[For Exercises see pp 197, 198]

PROPOSITION 28 THEOREM

In equal circles the arcs, which are cut off by equal chords, shall be equal, the major arc equal to the major arc, and the minor to the minor

Let ABC , DEF be two equal circles,
and let the chord BC = the chord EF
then shall the major arc BAC = the major arc EDF ,
and the minor arc BGC = the minor arc EHF .

Find K and L the centres of the $\odot^s ABC$, DEF III 1.
and join BK , KC , EL , LF

Then because the $\odot^s ABC$, DEF are equal,
their radii are equal

Hence in the $\triangle^s BKC$, ELF ,

Because $\left\{ \begin{array}{l} BK = EL, \\ KC = LF, \\ \text{and } BC = EF, \end{array} \right.$

the $\angle BKC$ = the $\angle ELF$,

the arc BGC = the arc EHF ,

and these are the minor arcs

Hyp

I 8

III 26

But the whole $\odot^ce ABGC$ = the whole $\odot^ce DEHF$, *Hyp.*

the remaining arc BAC = the remaining arc EDF .

and these are the major arcs Q L D.

PROPOSITION 29 THEOREM

In equal circles the chords, which cut off equal arcs, shall be equal

Let ABC, DEF be equal circles,
and let the arc BGC = the arc EHF
then shall the chord BC = the chord EF

Find K, L the centres of the circles

III 1

Join BK, KC, EL, LF

Then in the equal \circ^s ABC, DEF,
because the arc BGC = the arc EHF,
the $\angle BKC = \text{the } \angle ELF$

III 27

Hence in the Δ^s BKC, ELF,

Because { $BK = EL$, being radii of equal circles,
 $KC = LF$, for the same reason,
 and the $\angle BKC = \text{the } \angle ELF$,
 $BC = EF$

Proved

I 4

Q E D

EXERCISES

ON PROPOSITIONS 26, 27

- 1 *If two chords of a circle are parallel, they intercept equal arcs*
- 2 *The straight lines, which join the extremities of two equal arcs of a circle towards the same parts, are parallel*
- 3 *In a circle, or in equal circles, sectors are equal if their angles at the centres are equal*

4 If two chords of a circle intersect at right angles, the opposite arcs are together equal to a semicircumference

5 If two chords intersect within a circle, they form an angle equal to that subtended at the circumference by the sum of the arcs they cut off.

6 If two chords intersect without a circle, they form an angle equal to that subtended at the circumference by the difference of the arcs they cut off

7 If AB is a fixed chord of a circle, and P any point on one of the arcs cut off by it, then the bisector of the angle APB cuts the conjugate arc in the same point, whatever be the position of P.

8 Two circles intersect at A and B, and through these points straight lines are drawn from any point P on the circumference of one of the circles shew that when produced they intercept on the other circumference an arc which is constant for all positions of P

9 A triangle ABC is inscribed in a circle, and the bisectors of the angles meet the circumference at X, Y, Z Find each angle of the triangle XYZ in terms of those of the original triangle

ON PROPOSITIONS 28, 29

10 The straight lines which join the extremities of parallel chords in a circle (i) towards the same parts, (ii) towards opposite parts, are equal.

11 Through A, a point of intersection of two equal circles two straight lines PAQ, XAY are drawn. shew that the chord PX is equal to the chord QY

12 Through the points of intersection of two circles two parallel straight lines are drawn terminated by the circumferences shew that the straight lines which join their extremities towards the same parts are equal

13 Two equal circles intersect at A and B, and through A any straight line PAQ is drawn terminated by the circumferences shew that $BP=BQ$

14 ABC is an isosceles triangle inscribed in a circle, and the bisectors of the base angles meet the circumference at X and Y Shew that the figure BXAYC must have four of its sides equal.

What relation must subsist among the angles of the triangle ABC, in order that the figure BXAYC may be equilateral?

NOTE We have given Euclid's demonstrations of Propositions 26, 27, 28, 29, but it should be noticed that all these propositions also admit of direct proof by the method of *superposition*

To illustrate this method we will apply it to Proposition 26

PROPOSITION 26 [Alternative Proof]

In equal circles, the arcs which subtend equal angles, whether at the centres or circumferences, shall be equal

Let ABC , DEF be equal circles, and let the \angle^s BGC , EHF at the centres be equal, and consequently the \angle^s BAC , EDF at the C^{cs} equal III 20

then shall the arc $\text{BKC} = \text{the arc ELF}$

For if the O ABC be applied to the O DEF , so that the centre G may fall on the centre H ,

then because the circles are equal,

Hyp

their C^{cs} must coincide,

hence by revolving the upper circle about its centre, the lower circle remaining fixed,

B may be made to coincide with E ,

and consequently GB with HE

And because the $\angle \text{BGC} = \text{the } \angle \text{EHF}$,

GC must coincide with HF

and since $\text{GC} = \text{HF}$,

C must fall on F

Hyp

Now B coinciding with E , and C with F ,
and the C^{cs} of the O ABC with the C^{cs} of the O DEF ,

the arc BKC must coincide with the arc ELF

the arc $\text{BKC} = \text{the arc ELF}$

Q.E.D.

PROPOSITION 30 PROBLEM

To bisect a given arc

Let ADB be the given arc
it is required to bisect it

Join AB, and bisect it at C I 10

At C draw CD at rt angles to AB, meeting the given arc at D I 11

Then shall the arc ADB be bisected at D

Join AD, BD

Then in the \triangle^s ACD, BCD,

Because { $AC = BC,$ *Constr*
and CD is common;
and the $\angle ACD = \text{the } \angle BCD,$ being rt angles
 $\therefore AD = BD$ I 4

And since in the \odot ADB, the chords AD, BD are equal,
the arcs cut off by them are equal, the minor arc equal
to the minor, and the major arc to the major III 28

and the arcs AD, BD are both minor arcs,
for each is less than a semi-circumference, since DC, bisecting
the chord AB at rt angles, must pass through the centre
of the circle III 1. Cor

\therefore the arc AD = the arc BD

that is, the arc ADB is bisected at D Q E D

EXERCISES

1 If a tangent to a circle is parallel to a chord, the point of contact will bisect the arc cut off by the chord

2 Trisect a quadrant, or the fourth part of the circumference, of a circle

PROPOSITION 31 THEOREM

*The angle in a semicircle is a right angle
the angle in a segment greater than a semicircle is less
than a right angle,*

*and the angle in a segment less than a semicircle is
greater than a right angle*

Let ABCD be a circle, of which BC is a diameter, and E the centre, and let AC be a chord dividing the circle into the segments ABC, ADC, of which the segment ABC is greater, and the segment ADC less than a semicircle

then (i) the angle in the semicircle BAC shall be a rt angle,
(ii) the angle in the segment ABC shall be less than a rt. angle,

(iii) the angle in the segment ADC shall be greater than a rt angle

In the arc ADC take any point D,
Join BA, AD, DC, AE, and produce BA to F

(i) Then because $EA = EB$, III Def 1
the $\angle EAB = \text{the } \angle EBA$ I 5

And because $EA = EC$,
the $\angle EAC = \text{the } \angle ECA$

the whole $\angle BAC = \text{the sum of the } \angle^s \text{ EBA, ECA}$

but the ext $\angle FAC = \text{the sum of the two int } \angle^s \text{ CBA, BCA,}$
the $\angle BAC = \text{the } \angle FAC$,

these angles, being adjacent, are rt. angles
the $\angle BAC$, in the semicircle BAC, is a rt angle

(ii) In the $\triangle ABC$, because the two $\angle^s ABC, BAC$ are together less than two rt angles, I 17

and of these, the $\angle BAC$ is a rt. angle, Proved

\therefore the $\angle ABC$, which is the angle in the segment ABC , is less than a rt. angle

(iii) Because $ABCD$ is a quadrilateral inscribed in the $\odot ABC$,

\therefore the $\angle^s ABC, ADC$ together = two rt angles, III 22

and of these, the $\angle ABC$ is less than a rt angle Proved

\therefore the $\angle ADC$, which is the angle in the segment ADC , is greater than a rt. angle Q E D

EXERCISES

✓1 A circle described on the hypotenuse of a right-angled triangle as diameter, passes through the opposite angular point

✓2 A system of right-angled triangles is described upon a given straight line as hypotenuse. find the locus of the opposite angular points

✓3. A straight rod of given length slides between two straight rulers placed at right angles to one another. find the locus of its middle point.

4 Two circles intersect at A and B , and through A two diameters AP, AQ are drawn, one in each circle. show that the points P, B, Q are collinear [See Def p 102]

5 A circle is described on one of the equal sides of an isosceles triangle as diameter. Show that it passes through the middle point of the base

6 Of two circles which have internal contact, the diameter of the inner is equal to the radius of the outer. Shew that any chord of the outer circle, drawn from the point of contact, is bisected by the circumference of the inner circle

7. Circles described on any two sides of a triangle as diameters intersect on the third side, or the third side produced

8 Find the locus of the middle points of chords of a circle drawn through a fixed point

Distinguish between the cases when the given point is within, on, or without the circumference

9. Describe a square equal to the difference of two given squares

10 Through one of the points of intersection of two circles draw a chord of one circle which shall be bisected by the other

11 On a given straight line as base a system of equilateral four-sided figures is described. find the locus of the intersection of their diagonals

NOTE 1 The extension of Proposition 20 to *straight and reflex* angles furnishes a simple alternative proof of the first theorem contained in Proposition 31,
viz

The angle in a semicircle is a right angle

For, in the adjoining figure, the angle at the centre, standing on the arc BHC, is double the angle at the C^a , standing on the same arc

Now the angle at the centre is the *straight angle* BEC,
the $\angle BAC$ is half of the *straight angle* BEC
and a straight angle = two rt angles,
the $\angle BAC$ = one half of two rt angles,
= one rt angle

Q E D

NOTE 2 From Proposition 31 we may derive a simple practical solution of Proposition 17, namely,

To draw a tangent to a circle from a given external point

Let BCD be the given circle, and A the given external point

It is required to draw from A a tangent to the \odot BCD

Find E, the centre of the circle, and join AE

On AE describe the semicircle ABE, to cut the given circle at B

Join AB

Then AB shall be a tangent to the \odot BCD

For the $\angle ABE$, being in a semicircle, is a rt angle III 31

AB is drawn at rt angles to the radius EB, from its extremity B,

AB is a tangent to the circle III 16

Q E F

Since the semicircle might be described on either side of AE, it is clear that there will be a second solution of the problem, as shewn by the dotted lines of the figure

PROPOSITION 32. THEOREM.

If a straight line touch a circle, and from the point of contact a chord be drawn, the angles which this chord makes with the tangent shall be equal to the angles in the alternate segments of the circle

Let EF touch the given $\odot ABC$ at B, and let BD be a chord drawn from B, the point of contact

then shall (1) the $\angle DBF =$ the angle in the alternate segment BAD:

(2) the $\angle DBE =$ the angle in the alternate segment BCD.

From B draw BA perp to EF I 11
 Take any point C in the arc BD,
 and join AD, DC, CB

(1) Then because BA is drawn perp to the tangent EF, at its point of contact B,

BA passes through the centre of the circle III 19
 the $\angle ADB$, being in a semicircle, is a rt angle III 31
 in the $\triangle ABD$, the other \angle^s ABD, BAD together = a rt
 angle, I 32

that is, the \angle^s ABD, BAD together = the $\angle ABF$

From these equals take the common $\angle ABD$,
 the $\angle DBF =$ the $\angle BAD$, which is in the alternate segment

(11) Because ABCD is a quadrilateral inscribed in a circle,

the \angle^s BCD, BAD together = two rt angles III 22

but the \angle^s DBE, DBF together = two rt angles, I 13.

the \angle^s DBE, DBF together = the \angle^s BCD, BAD

and of these the \angle DBF = the \angle BAD, *Proved*

the \angle DBE = the \angle DCB, which is in the alternate segment Q F D

EXERCISES

- 1 State and prove the converse of this proposition
- 2 Use this Proposition to shew that the tangents drawn to a circle from an external point are equal
- 3 If two circles touch one another, any straight line drawn through the point of contact cuts off similar segments
Prove this for (i) internal, (ii) external contact
- 4 If two circles touch one another, and from A, the point of contact, two chords APQ, AXY are drawn then PX and QY are parallel
Prove this for (i) internal, (ii) external contact
- 5 Two circles intersect at the points A, B and one of them passes through O, the centre of the other prove that OA bisects the angle between the common chord and the tangent to the first circle at A
- 6 Two circles intersect at A and B, and through P, any point on the circumferences of one of them, straight lines PAC, PBD are drawn to cut the other circle at C and D shew that CD is parallel to the tangent at P
- 7 If from the point of contact of a tangent to a circle, a chord be drawn, the perpendiculars dropped on the tangent and chord from the middle point of either are cut off by the chord are equal

PROPOSITION 33. PROBLEM

On a given straight line to describe a segment of a circle which shall contain an angle equal to a given angle

Let AB be the given st line, and C the given angle it is required to describe on AB a segment of a circle which shall contain an angle equal to C.

At A in BA, make the $\angle BAD$ equal to the $\angle C$ I 23

From A draw AE at rt angles to AD. I 11

Bisect AB at F, I 10

and from F draw FG at rt angles to AB, cutting AE at G

Join GB

Then in the Δ^s AFG, BFG

Because $\left\{ \begin{array}{l} AF = BF, \\ \text{and FG is common,} \\ \text{and the } \angle AFG = \text{the } \angle BFG, \text{ being rt angles,} \\ GA = GB \end{array} \right. \quad \begin{array}{l} \text{Constr} \\ \\ \\ \text{I 4} \end{array}$

the circle described from centre G, with radius GA, will pass through B

Describe this circle, and call it ABH:

then the segment AHB shall contain an angle equal to C

Because AD is drawn at rt. angles to the radius GA from its extremity A,

AD is a tangent to the circle III 16

and from A, its point of contact, a chord AB is drawn,

\therefore the $\angle BAD =$ the angle in the alt segment AHB III 32

But the $\angle BAD =$ the $\angle C$. Constr

\therefore the angle in the segment AHB = the $\angle C$

AHB is the segment required Q E F

NOTE In the particular case when the given angle C is a rt angle, the segment required will be the semicircle described on the given st line AB , for the angle in a semicircle is a rt angle in 31

EXERCISES

[The following exercises depend on the corollary to Proposition 21 given on page 187, namely

The locus of the vertices of triangles which stand on the same base and have a given vertical angle, is the arc of the segment standing on this base, and containing an angle equal to the given angle

Exercises 1 and 2 afford good illustrations of the method of finding required points by the *Intersection of Loci*. See page 117.]

1 Describe a triangle on a given base, having a given vertical angle, and having its vertex on a given straight line

2 Construct a triangle, having given the base, the vertical angle and

- (i) one other side
- (ii) the altitude
- (iii) the length of the median which bisects the base
- (iv) the point at which the perpendicular from the vertex meets the base

3 Construct a triangle having given the base, the vertical angle, and the point at which the base is cut by the bisector of the vertical angle

[Let AB be the base, X the given point in it, and K the given angle. On AB describe a segment of a circle containing an angle equal to K , complete the \odot^o by drawing the arc APB . Bisect the arc APB at P . Join PX , and produce it to meet the \odot^o at C . Then ABC shall be the required triangle.]

4 Construct a triangle having given the base, the vertical angle, and the sum of the remaining sides

[Let AB be the given base, K the given angle, and H the given line equal to the sum of the sides. On AB describe a segment containing an angle equal to K , also another segment containing an angle equal to half the $\angle K$. From centre A , with radius H , describe a circle cutting the last drawn segment at X and Y . Join AX (or AY) cutting the first segment at C . Then ABC shall be the required triangle.]

5 Construct a triangle having given the base, the vertical angle, and the difference of the remaining sides

PROPOSITION 34 PROBLEM

From a given circle to cut off a segment which shall contain an angle equal to a given angle

Let ABC be the given circle, and D the given angle it is required to cut off from the $\odot ABC$ a segment which shall contain an angle equal to D

Take any point B on the \odot^{ce} ,
and at B draw the tangent EBF III 17

At B , in FB , make the $\angle FBC$ equal to the $\angle D$ I 23

Then the segment BAC shall contain an angle equal to D

Because EF is a tangent to the circle, and from B , its point of contact, a chord BC is drawn,

the $\angle FBC =$ the angle in the alternate segment BAC

But the $\angle FBC =$ the $\angle D$, III 32

the angle in the segment $BAC =$ the $\angle D$ *Const*

Hence from the given $\odot ABC$ a segment BAC has been cut off, containing an angle equal to D Q E F

EXERCISES.

1 The chord of a given segment of a circle is produced to a fixed point on this straight line so produced draw a segment of a circle similar to the given segment

2 Through a given point without a circle draw a straight line that will cut off a segment capable of containing an angle equal to a given angle

PROPOSITION 35 THEOREM

If two chords of a circle cut one another, the rectangle contained by the segments of one shall be equal to the rectangle contained by the segments of the other

Let AB, CD, two chords of the \odot ACBD, cut one another at E

then shall the rect AE, EB = the rect. CE, ED

Find F the centre of the \odot ACB III 1

From F draw FG, FH perp respectively to AB, CD I 12

Join FA, FE, FD

Then because FG is drawn from the centre F perp to AB,
AB is bisected at G III. 3

For a similar reason CD is bisected at H

Again, because AB is divided equally at G, and unequally at E,
the rect AE, EB with the sq on EG = the sq on AG II 5

To each of these equals add the sq on GF,
then the rect AE, EB with the sqq on EG, GF = the sum of
the sqq on AG, GF

But the sqq on EG, GF = the sq on FE, I 47

and the sqq on AG, GF = the sq on AF,

for the angles at G are rt angles

the rect AE, EB with the sq on FE = the sq on AF

Similarly it may be shewn that

the rect. CE, ED with the sq on FE = the sq on FD

But the sq on AF = the sq on FD, for AF = FD

. the rect AE, EB with the sq on FE = the rect. CE, ED
with the sq on FE.

From these equals take the sq on FE

then the rect AE, EB = the rect CE, ED Q E D

COROLLARY *If through a fixed point within a circle any number of chords are drawn, the rectangles contained by their segments are all equal*

NOTE The following special cases of this proposition deserve notice

- (i) when the given chords both pass through the centre
- (ii) when one chord passes through the centre, and cuts the other at right angles
- (iii) when one chord passes through the centre, and cuts the other obliquely.

In each of these cases the general proof requires some modification, which may be left as an exercise to the student

EXERCISES

1. Two straight lines AB , CD intersect at E , so that the rectangle AE , EB is equal to the rectangle CE , ED shew that the four points A , B , C , D are concyclic.

2 The rectangle contained by the segments of any chord drawn through a given point within a circle is equal to the square on half the shortest chord which may be drawn through that point

3 ABC is a triangle right-angled at C , and from C a perpendicular CD is drawn to the hypotenuse shew that the square on CD is equal to the rectangle AD , DB

4 ABC is a triangle, and AP , BQ the perpendiculars dropped from A and B on the opposite sides, intersect at O shew that the rectangle AO , OP is equal to the rectangle BO , OQ

5 Two circles intersect at A and B , and through any point in AB their common chord two chords are drawn, one in each circle; shew that their four extremities are concyclic

6 A and B are two points within a circle such that the rectangle contained by the segments of any chord drawn through A is equal to the rectangle contained by the segments of any chord through B shew that A and B are equidistant from the centre

7 If through E , a point without a circle, two secants EAB , ECD are drawn, shew that the rectangle EA , EB is equal to the rectangle EC , ED

[Proceed as in III 35, using II 6]

8 Through A , a point of intersection of two circles, two straight lines CAE , DAF are drawn, each passing through a centre and terminated by the circumferences shew that the rectangle CA , AE is equal to the rectangle DA , AF

PROPOSITION 36 THEOREM

If from any point without a circle a tangent and a secant be drawn, then the rectangle contained by the whole secant and the part of it without the circle shall be equal to the square on the tangent

Let ABC be a circle, and from D a point without it, let there be drawn the secant DCA, and the tangent DB

then the rect DA, DC shall be equal to the sq on DB

Find E, the centre of the \odot ABC III 1

and from E, draw EF perp to AD I 12

Join EB, EC, ED

Then because EF, passing through the centre, is perp to the chord AC,

AC is bisected at F III 3

And since AC is bisected at F and produced to D,
the rect DA, DC with the sq on FC = the sq on FD II 6

To each of these equals add the sq on EF
then the rect DA, DC with the sqq on EF, FC = the sqq on EF, FD

But the sqq on EF, FC = the sq on EC, for EFC is a rt angle,
= the sq on EB

And the sqq on EF, FD = the sq on ED, for EFD is a rt angle,
= the sqq on EB, BD, for EBD is a
rt angle III

the rect DA, DC with the sq on EB = the sqq on EB, BD

From these equals take the sq on EB

then the rect DA, DC = the sq on DB Q.E.D.

NOTE This proof may easily be adapted to the case when the secant passes through the centre of the circle

COROLLARY *If from a given point without a circle any number of secants are drawn, the rectangles contained by the whole secants and the parts of them without the circle are all equal, for each of these rectangles is equal to the square on the tangent drawn from the given point to the circle*

For instance, in the adjoining figure, each of the rectangles PB, PA and PD, PC and PF, PE is equal to the square on the tangent PQ.

the rect PB, PA

= the rect PD, PC

= the rect PF, PE

NOTE Remembering that the segments into which the chord AB is divided at P, are the lines PA, PB, (see Part I page 131) we are enabled to include the corollaries of Propositions 35 and 36 in a single enunciation

If any number of chords of a circle are drawn through a given point within or without a circle, the rectangles contained by the segments of the chords are equal

EXERCISES

1 Use this proposition to shew that tangents drawn to a circle from an external point are equal

2 If two circles intersect, tangents drawn to them from any point in their common chord produced are equal

3 If two circles intersect at A and B, and PQ is a tangent to both circles, shew that AB produced bisects PQ

4 If P is any point on the straight line AB produced, shew that the tangents drawn from P to all circles which pass through A and B are equal

5 ABC is a triangle right-angled at C, and from any point P in AC, a perpendicular PQ is drawn to the hypotenuse. shew that the rectangle AC, AP is equal to the rectangle AB, AQ

6 ABC is a triangle right-angled at C, and from C a perpendicular CD is drawn to the hypotenuse shew that the rect AB, AD is equal to the square on AC

PROPOSITION 37 THEOREM

If from a point without a circle there be drawn two straight lines, one of which cuts the circle, and the other meets it, and if the rectangle contained by the whole line which cuts the circle and the part of it without the circle be equal to the square on the line which meets the circle, then the line which meets the circle shall be a tangent to it

Let ABC be a circle, and from D, a point without it, let there be drawn two st lines DCA and DB, of which DCA cuts the circle at C and A, and DB meets it, and let the rect DA, DC = the sq on DB

then shall DB be a tangent to the circle

From D draw DE to touch the \odot ABC III. 17

let E be the point of contact

Find the centre F, and join FB, FD, FE. III. 1

Then since DCA is a secant, and DE a tangent to the circle, the rect DA, DC = the sq on DE, III. 36

But, by Hypothesis, the rect DA, DC = the sq on DB,
the sq on DE = the sq on DB,
DE = DB

Hence in the \triangle DBF, DEF

Because $\begin{cases} \text{DB} = \text{DE}, \\ \text{and BF} = \text{EF}, \\ \text{and DF is common,} \end{cases}$ Proved
III Def 1

the \angle DBF = the \angle DEF I 8

But DEF is a rt angle, III 18

DBF is also a rt angle,

and since BF is a radius,

DB touches the \odot ABC at the point B

Q. E. D

NOTE ON THE METHOD OF LIMITS AS APPLIED TO TANGENCY

Euclid defines a tangent to a circle as *a straight line which meets the circumference, but being produced, does not cut it* and from this definition he deduces the fundamental theorem that a tangent is perpendicular to the radius drawn to the point of contact Prop 16

But this result may also be established by the Method of Limits, which regards the tangent as *the ultimate position of a secant when its two points of intersection with the circumference are brought into coincidence* [See Note on page 151] and it may be shewn that every theorem relating to the tangent may be derived from some more general proposition relating to the secant, by considering the ultimate case when the two points of intersection coincide.

1 To prove by the Method of Limits that a tangent to a circle is at right angles to the radius drawn to the point of contact

Let ABD be a circle, whose centre is C, and PABQ a secant cutting the C^o in A and B, and let P'AQ' be the limiting position of PQ when the point B is brought into coincidence with A. then shall CA be perp to P'Q'

Bisect AB at E and join CE
then CE is perp to PQ III 3

Now let the secant PABQ change its position in such a way that while the point A remains fixed, the point B continually approaches A, and ultimately coincides with it,

then, *however near B approaches to A*, the st line CE is always perp to PQ, since it joins the centre to the middle point of the chord AB

But in the limiting position, when B coincides with A, and the secant PQ becomes the tangent P'Q', it is clear that the point E will also coincide with A, and the perpendicular CE becomes the radius CA. Hence CA is perp to the tangent P'Q' at its point of contact A. Q E D.

NOTE It follows from Proposition 2 that *a straight line cannot cut the circumference of a circle at more than two points* Now when the two points in which a secant cuts a circle move towards coincidence, the secant ultimately becomes a tangent to the circle we infer therefore that a tangent cannot meet a circle otherwise than at its point of contact Thus Euclid's definition of a tangent may be deduced from that given by the Method of Limits

2 By this Method Proposition 32 may be derived as a special case from Proposition 21.

For let A and B be two points on the C^e of the $\odot ABC$, and let $\angle BCA$, $\angle BPA$ be any two angles in the segment $BCPA$ then the $\angle BPA = \angle BCA$ III 21

Produce PA to Q.

Now let the point P continually approach the fixed point A, and ultimately coincide with it,

then, however near P may approach to A, the $\angle BPQ = \angle BCA$ III 21

But in the limiting position when P coincides with A,

and the secant PAQ becomes the tangent AQ',

it is clear that BP will coincide with BA,

and the $\angle BPQ$ becomes the $\angle BAQ'$

Hence the $\angle BAQ' = \angle BCA$, in the alternate segment Q E D

The contact of circles may be treated in a similar manner by adopting the following definition

DEFINITION If one or other of two intersecting circles alters its position in such a way that the two points of intersection continually approach one another, and ultimately coincide, in the limiting position they are said to touch one another, and the point in which the two points of intersection ultimately coincide is called the point of contact

EXAMPLES ON LIMITS

1 Deduce Proposition 19 from the Corollary of Proposition 1 and Proposition 3

2 Deduce Propositions 11 and 12 from Ex 1, page 156

3 Deduce Proposition 6 from Proposition 5

4 Deduce Proposition 13 from Proposition 10

5 Shew that a straight line cuts a circle in two different points, two coincident points, or not at all, according as its distance from the centre is less than, equal to, or greater than a radius

6 Deduce Proposition 32 from Ex 3, page 188

7 Deduce Proposition 36 from Ex 7, page 209

8 The angle in a semi-circle is a right angle

To what Theorem is this statement reduced, when the vertex of the right angle is brought into coincidence with an extremity of the diameter?

9 From Ex 1, page 190, deduce the corresponding property of a triangle inscribed in a circle.

THEOREMS AND EXAMPLES ON BOOK III.

I ON THE CENTRE AND CHORDS OF A CIRCLE

See Propositions 1, 3, 14, 15, 25

1 *All circles which pass through a fixed point, and have their centres on a given straight line, pass also through a second fixed point.*

Let AB be the given st line, and P the given point.

From P draw PR perp to AB;
and produce PR to P', making RP' equal to PR

Then all circles which pass through P, and have their centres on AB, shall pass also through P'.

For let C be the centre of *any* one of these circles.

Join CP, CP'

Then in the Δ^s CRP, CRP'

Because { $\begin{array}{l} \text{CR is common,} \\ \text{and } RP = RP', \\ \text{and the } \angle CRP = \text{the } \angle CRP', \text{ being rt angles,} \\ \text{CP} = \text{CP}', \end{array}$ Constr
1 4

the circle whose centre is C, and which passes through P, must pass also through P'.

But C is the centre of *any* circle of the system;
all circles, which pass through P, and have their centres in AB,
pass also through P' Q E D

2 *Describe a circle that shall pass through three given points not in the same straight line*

3 Describe a circle that shall pass through two given points and have its centre in a given straight line. When is this impossible?

4 Describe a circle of given radius to pass through two given points. When is this impossible?

5 ABC is an isosceles triangle, and from the vertex A , as centre, a circle is described cutting the base, or the base produced, at X and Y . Shew that $BX = CY$.

6 If two circles which intersect are cut by a straight line parallel to the common chord, shew that the parts of it intercepted between the circumferences are equal.

7 If two circles cut one another, any two straight lines drawn through a point of section, making equal angles with the common chord, and terminated by the circumferences, are equal. [Ex 12, p 156]

8 If two circles cut one another, of all straight lines drawn through a point of section and terminated by the circumferences, the greatest is that which is parallel to the line joining the centres.

9 Two circles, whose centres are C and D , intersect at A , B , and through A a straight line PAQ is drawn terminated by the circumferences. If PC , QD intersect at X , shew that the angle PXQ is equal to the angle CAD .

10 Through a point of section of two circles which cut one another draw a straight line terminated by the circumferences and bisected at the point of section.

11 AB is a fixed diameter of a circle, whose centre is C , and from P , any point on the circumference, PQ is drawn perpendicular to AB , shew that the bisector of the angle CPQ always intersects the circle in one or other of two fixed points.

12 Circles are described on the sides of a quadrilateral as diameters. shew that the common chord of any two consecutive circles is parallel to the common chord of the other two. [Ex 9, p 97]

13 Two equal circles touch one another externally, and through the point of contact two chords are drawn, one in each circle, at right angles to each other. shew that the straight line joining their extremities is equal to the diameter of either circle.

14 Straight lines are drawn from a given external point to the circumference of a circle. find the locus of their middle points. [Ex 3, p 97]

15 Two equal segments of circles are described on opposite sides of the same chord AB , and through O , the middle point of AB , any straight line POQ is drawn, intersecting the arcs of the segments at P and Q . shew that $OP = OQ$.

II ON THE TANGENT AND THE CONTACT OF CIRCLES

See Propositions 11, 12, 16, 17, 18, 19

1 All equal chords placed in a given circle touch a fixed concentric circle

2 If from an external point two tangents are drawn to a circle, the angle contained by them is double the angle contained by the chord of contact and the diameter drawn through one of the points of contact.

3. Two circles touch one another externally, and through the point of contact a straight line is drawn terminated by the circumferences. shew that the tangents at its extremities are parallel

4 Two circles intersect, and through one point of section any straight line is drawn terminated by the circumferences shew that the angle between the tangents at its extremities is equal to the angle between the tangents at the point of section

5 Shew that two parallel tangents to a circle intercept on any third tangent a segment which subtends a right angle at the centre

6 Two tangents are drawn to a given circle from a fixed external point A, and any third tangent cuts them produced at P and Q. shew that PQ subtends a constant angle at the centre of the circle.

7. In any quadrilateral circumscribed about a circle, the sum of one pair of opposite sides is equal to the sum of the other pair.

8 If the sum of one pair of opposite sides of a quadrilateral is equal to the sum of the other pair, shew that a circle may be inscribed in the figure

[Bisect two adjacent angles of the figure, and so describe a circle to touch three of its sides Then prove indirectly by means of the last exercise that this circle must also touch the fourth side]

9. Two circles touch one another internally: shew that of all chords of the outer circle which touch the inner, the greatest is that which is perpendicular to the straight line joining the centres.

10 In a right-angled triangle, if a circle is described from the middle point of the hypotenuse as centre and with a radius equal to half the sum of the sides containing the right angle, it will touch the circles described on these sides as diameters

11. Through a given point, draw a straight line to cut a circle, so that the part intercepted by the circumference may be equal to a given straight line

In order that the problem may be possible, between what limits must the given line lie, when the given point is (i) without the circle, (ii) within it?

12 A series of circles touch a given straight line at a given point shew that the tangents to them at the points where they cut a given parallel straight line all touch a fixed circle, whose centre is the given point

13 If two circles touch one another internally, and any third circle be described touching both, then the sum of the distances of the centre of this third circle from the centres of the two given circles is constant.

14 Find the locus of points such that the pairs of tangents drawn from them to a given circle contain a constant angle

15 Find a point such that the tangents drawn from it to two given circles may be equal to two given straight lines When is this impossible?

16 If three circles touch one another two and two, prove that the tangents drawn to them at the three points of contact are concurrent and equal.

THE COMMON TANGENTS TO TWO CIRCLES

17. To draw a common tangent to two circles

First, if the given circles are external to one another, or if they intersect

Let A be the centre of the greater circle, and B the centre of the less

From A, with radius equal to the diff^{ce} of the radii of the given circles, describe a circle and from B draw BC to touch the last drawn circle Join AC, and produce it to meet the greater of the given circles at D

Through B draw the radius BE par^l to AD, and in the same direction

Join DE

then DE shall be a common tangent to the two given circles

For since $AC = \text{the diff}^{\text{ce}}$ between AD and BE,

$CD = BE$

Constr

and CD is par^l to BE,

Constr

DE is equal and par^l to CB

I 33

But since BC is a tangent to the circle at C,

the $\angle ACB$ is a rt angle,

III 18

hence each of the angles at D and E is a rt angle

I 29

DE is a tangent to both circles

Q E F.

It follows from hypothesis that the point B is outside the circle used in the construction

two tangents such as BC may always be drawn to it from B, hence two common tangents may always be drawn to the given circles by the above method. These are called the **direct common tangents**

When the given circles are external to one another and do not intersect, two more common tangents may be drawn

For, from centre A, with a radius equal to the sum of the radii of the given circles, describe a circle

From B draw a tangent to this circle, and proceed as before, but draw BE in the direction *opposite* to AD.

It follows from hypothesis that B is external to the circle used in the construction,

two tangents may be drawn to it from B

Hence two more common tangents may be drawn to the given circles. these will be found to pass between the given circles, and are called the **transverse common tangents**

Thus, in general, *four* common tangents may be drawn to two given circles

The student should investigate for himself the number of common tangents which may be drawn in the following special cases, noting in each case where the general construction fails, or is modified —

- (i) When the given circles intersect.
- (ii) When the given circles have external contact
- (iii) When the given circles have internal contact.
- (iv) When one of the given circles is wholly within the other.

18 *Draw the direct common tangents to two equal circles*

19 If the two direct, or the two transverse, common tangents are drawn to two circles, the parts of the tangents intercepted between the points of contact are equal.

20 If four common tangents are drawn to two circles external to one another, shew that the two direct, and also the two transverse, tangents intersect on the straight line which joins the centres of the circles

21. Two given circles have external contact at A, and a direct common tangent is drawn to touch them at P and Q shew that PQ subtends a right angle at the point A

22. Two circles have external contact at A, and a direct common tangent is drawn to touch them at P and Q shew that a circle described on PQ as diameter is touched at A by the straight line which joins the centres of the circles.

23 Two circles whose centres are C and C' have external contact at A , and a direct common tangent is drawn to touch them at P and Q shew that the bisectors of the angles PCA , $QC'A$ meet at right angles in PQ . And if R is the point of intersection of the bisectors, shew that RA is also a common tangent to the circles

24 Two circles have external contact at A , and a direct common tangent is drawn to touch them at P and Q shew that the square on PQ is equal to the rectangle contained by the diameters of the circles

25 Draw a tangent to a given circle, so that the part of it intercepted by another given circle may be equal to a given straight line. When is this impossible?

26 Draw a secant to two given circles, so that the parts of it intercepted by the circumferences may be equal to two given straight lines

PROBLEMS ON TANGENCY

The following exercises are solved by the Method of Intersection of Loci, explained on page 117

The student should begin by making himself familiar with the following loci

(i) *The locus of the centres of circles which pass through two given points*

(ii) *The locus of the centres of circles which touch a given straight line at a given point*

(iii) *The locus of the centres of circles which touch a given circle at a given point*

(iv) *The locus of the centres of circles which touch a given straight line, and have a given radius*

(v) *The locus of the centres of circles which touch a given circle, and have a given radius*

(vi) *The locus of the centres of circles which touch two given straight lines*

In each exercise the student should investigate the limits and relations among the data, in order that the problem may be possible

27 Describe a circle to touch three given straight lines

28 Describe a circle to pass through a given point and touch a given straight line at a given point

29 Describe a circle to pass through a given point, and touch a given circle at a given point.

30 Describe a circle of given radius to pass through a given point, and touch a given straight line

31 Describe a circle of given radius to touch two given circles

32 Describe a circle of given radius to touch two given straight lines

33 Describe a circle of given radius to touch a given circle and a given straight line

34 Describe two circles of given radii to touch one another and a given straight line, on the same side of it

35 If a circle touches a given circle and a given straight line, shew that the points of contact and an extremity of the diameter of the given circle at right angles to the given line are collinear

36 To describe a circle to touch a given circle, and also to touch a given straight line at a given point

Let DEB be the given circle, PQ the given st line, and A the given point in it

it is required to describe a circle to touch the \odot DEB, and also to touch PQ at A

At A draw AF perp to PQ r 11 then the centre of the required circle must lie in AF.

Find C, the centre of the \odot DEB, r 1

and draw a diameter BD perp to PQ

join A to one extremity D, cutting the \odot^{co} at E.

Join CE, and produce it to cut AF at F

Then F is the centre, and FA the radius of the required circle

[Supply the proof and shew that a second solution is obtained by joining AB, and producing it to meet the \odot^{co} .

also distinguish between the nature of the contact of the circles, when PQ cuts, touches, or is without the given circle]

37. Describe a circle to touch a given straight line, and to touch a given circle at a given point

38 Describe a circle to touch a given circle, have its centre in a given straight line, and pass through a given point in that straight line

[For other problems of the same class see page 235]

ORTHOGONAL CIRCLES

DEFINITION Circles which intersect at a point, so that the two tangents at that point are at right angles to one another, are said to be **orthogonal**, or to cut one another **orthogonally**

39 In two intersecting circles the angle between the tangents at one point of intersection is equal to the angle between the tangents at the other.

40 If two circles cut one another orthogonally, the tangent to each circle at a point of intersection will pass through the centre of the other circle

41 If two circles cut one another orthogonally, the square on the distance between their centres is equal to the sum of the squares on their radii

42 Find the locus of the centres of all circles which cut a given circle orthogonally at a given point

43 Describe a circle to pass through a given point and cut a given circle orthogonally at a given point

III ON ANGLES IN SEGMENTS, AND ANGLES AT THE CENTRES AND CIRCUMFERENCES OF CIRCLES

See Propositions 20, 21, 22, 26, 27, 28, 29, 31, 32, 33, 34

1 If two chords intersect within a circle, they form an angle equal to that at the centre, subtended by half the sum of the arcs they cut off

Let AB and CD be two chords, intersecting at E within the given \odot ADBC
then shall the \angle AEC be equal to the angle at the centre, subtended by half the sum of the arcs AC, BD

Join AD

Then the ext \angle AEC = the sum of the int opp \angle 's EDA, EAD,

that is, the sum of the \angle 's CDA, BAD

But the \angle 's CDA, BAD are the angles at the \odot subtended by the arcs AC, BD,

. their sum = half the sum of the angles at the centre subtended by the same arcs,

or, the \angle AEC = the angle at the centre subtended by half the sum of the arcs AC, BD.

Q. E. D

2 If two chords when produced intersect outside a circle, they form an angle equal to that at the centre subtended by half the difference of the arcs they cut off

3 The sum of the arcs cut off by two chords of a circle at right angles to one another is equal to the semi-circumference

4 AB, AC are any two chords of a circle, and P, Q are the middle points of the minor arcs cut off by them if PQ is joined, cutting AB and AC at X, Y, shew that $AX = AY$.

5 If one side of a quadrilateral inscribed in a circle is produced, the exterior angle is equal to the opposite interior angle

6 If two circles intersect, and any straight lines are drawn, one through each point of section, terminated by the circumferences, shew that the chords which join their extremities towards the same parts are parallel

7 ABCD is a quadrilateral inscribed in a circle, and the opposite sides AB, DC are produced to meet at P, and CB, DA to meet at Q if the circles circumscribed about the triangles PBC, QAB intersect at R, shew that the points P, R, Q are collinear

8 If a circle is described on one of the sides of a right-angled triangle, then the tangent drawn to it at the point where it cuts the hypotenuse bisects the other side

9 Given three points not in the same straight line shew how to find any number of points on the circle which passes through them, without finding the centre

10 Through any one of three given points not in the same straight line, draw a tangent to the circle which passes through them, without finding the centre

11 Of two circles which intersect at A and B, the circumference of one passes through the centre of the other from A any straight line ACD is drawn to cut them both, shew that $CB = CD$

12 Two tangents AP, AQ are drawn to a circle, and B is the middle point of the arc PQ, convex to A. Shew that PB bisects the angle APQ.

13 Two circles intersect at A and B, and at A tangents are drawn, one to each circle, to meet the circumferences at C and D if CB, BD are joined, shew that the triangles ABC, DBA are equiangular to one another

14 Two segments of circles are described on the same chord and on the same side of it; the extremities of the common chord are joined to any point on the arc of the exterior segment: shew that the arc intercepted on the interior segment is constant.

15 If a series of triangles are drawn standing on a fixed base, and having a given vertical angle, shew that the bisectors of the vertical angles all pass through a fixed point

16 ABC is a triangle inscribed in a circle, and E the middle point of the arc subtended by BC on the side remote from A if through E a diameter ED is drawn, shew that the angle DEA is half the difference of the angles at B and C [See Ex 7, p 101]

17 If two circles touch each other internally at a point A , any chord of the exterior circle which touches the interior is divided at its point of contact into segments which subtend equal angles at A

18 If two circles touch one another internally, and a straight line is drawn to cut them, the segments of it intercepted between the circumferences subtend equal angles at the point of contact

THE ORTHOCENTRE OF A TRIANGLE

19 The perpendiculars drawn from the vertices of a triangle to the opposite sides are concurrent

In the $\triangle ABC$, let AD , BE be the perp^s drawn from A and B to the opposite sides, and let them intersect at O . Join CO , and produce it to meet AB at F .

It is required to shew that CF is perp to AB .

Join DE .

Then, because the \angle 's OEC , ODC are rt angles,

Hyp

the points O , E , C , D are concyclic
the $\angle DEC =$ the $\angle DOC$, in the same segment,
 $=$ the vert opp $\angle FOA$

Again, because the \angle 's AEB , ADB are rt angles,

Hyp

the points A , E , D , B are concyclic
the $\angle DEB =$ the $\angle DAB$, in the same segment

the sum of the \angle 's FOA , $FAO =$ the sum of the \angle 's DEC , DEB
 $=$ a rt angle

the remaining $\angle AFO =$ a rt angle

Hyp
1 32

that is, CF is perp to AB

Hence the three perp^s AD , BE , CF meet at the point O Q.E.D.

[For an Alternative Proof see page 106]

DEFINITIONS

(i) The intersection of the perpendiculars drawn from the vertices of a triangle to the opposite sides is called its **orthocentre**

(ii) The triangle formed by joining the feet of the perpendiculars is called the **pedal or orthocentric triangle**. ✓

20 In an acute-angled triangle the perpendiculars drawn from the vertices to the opposite sides bisect the angles of the pedal triangle through which they pass

In the acute angled $\triangle ABC$, let AD , BE , CF be the perp^s drawn from the vertices to the opposite sides, meeting at the orthocentre O , and let DEF be the pedal triangle

then shall AD , BE , CF bisect respectively the \angle 's FDE , DEF , EFD

For, as in the last theorem, it may be shewn that the points O , D , C , E are concyclic,

the $\angle ODE = \text{the } \angle OCE$, in the same segment

Similarly the points O , D , B , F are concyclic,

the $\angle ODF = \text{the } \angle OBF$, in the same segment

But the $\angle OCE = \text{the } \angle OBF$, each being the comp^t of the $\angle BAC$
the $\angle ODE = \text{the } \angle ODF$

Similarly it may be shewn that the \angle 's DEF , EFD are bisected by BE and CF

Q E D

COROLLARY (i) Every two sides of the pedal triangle are equally inclined to that side of the original triangle in which they meet

For the $\angle EDC = \text{the comp}^t \text{ of the } \angle ODE$
 $= \text{the comp}^t \text{ of the } \angle OCE$
 $= \text{the } \angle BAC$

Similarly it may be shewn that the $\angle FDB = \text{the } \angle BAC$,
the $\angle EDC = \text{the } \angle FDB = \text{the } \angle A$

In like manner it may be proved that

the $\angle DEC = \text{the } \angle FEA = \text{the } \angle B$,
and the $\angle DFB = \text{the } \angle EFA = \text{the } \angle C$

COROLLARY. (ii) The triangles DEC , AEF , DBF are equiangular to one another and to the triangle ABC

NOTE If the angle BAC is obtuse, then the perpendiculars BE , CF bisect externally the corresponding angles of the pedal triangle

21 In any triangle, if the perpendiculars drawn from the vertices on the opposite sides are produced to meet the circumscribed circle, then each side bisects that portion of the line perpendicular to it which lies between the orthocentre and the circumference

Let ABC be a triangle in which the perpendiculars AD , BE are drawn, intersecting at O the orthocentre, and let AD be produced to meet the O° of the circumscribing circle at G
then shall $DO = DG$

Join BG

Then in the two $\triangle OEA$, ODB ,
the $\angle OEA = \text{the } \angle ODB$, being rt angles,
and the $\angle EOA = \text{the vert opp } \angle DOB$,
the remaining $\angle EAO = \text{the remaining } \angle DBO$. I 32

But the $\angle CAG = \text{the } \angle CBG$, in the same segment,
tho $\angle DBO = \text{the } \angle DBG$

Then in the $\triangle DBO$, DBG ,

Because $\begin{cases} \text{the } \angle DBO = \text{the } \angle DBG, \\ \text{the } \angle BDO = \text{the } \angle BDG, \\ \text{and } BD \text{ is common,} \end{cases}$
 $DO = DG$

Proved

I 26

Q E D

22 In an acute angled triangle the three sides are the external bisectors of the angles of the pedal triangle and in an obtuse-angled triangle the sides containing the obtuse angle are the internal bisectors of the corresponding angles of the pedal triangle

23 If O is the orthocentre of the triangle ABC , shew that the angles BOC , BAC are supplementary

24 If O is the orthocentre of the triangle ABC , then any one of the four points O , A , B , C is the orthocentre of the triangle whose vertices are the other three

25 The three circles which pass through two vertices of a triangle and its orthocentre are each equal to the circle circumscribed about the triangle

26 D , E are taken on the circumference of a semicircle described on a given straight line AB the chords AD , BE and AE , BD intersect (produced if necessary) at F and G shew that FG is perpendicular to AB

27 $ABCD$ is a parallelogram, AE and CE are drawn at right angles to AB , and CB respectively shew that ED , if produced, will be perpendicular to AC

28 ABC is a triangle, O is its orthocentre, and AK a diameter of the circumscribed circle shew that $BOCK$ is a parallelogram

29 The orthocentre of a triangle is joined to the middle point of the base, and the joining line is produced to meet the circumscribed circle prove that it will meet it at the same point as the diameter which passes through the vertex

30 The perpendicular from the vertex of a triangle on the base, and the straight line joining the orthocentre to the middle point of the base, are produced to meet the circumscribed circle at P and Q . shew that PQ is parallel to the base

31 The distance of each vertex of a triangle from the orthocentre is double of the perpendicular drawn from the centre of the circumscribed circle on the opposite side.

32 Three circles are described each passing through the orthocentre of a triangle and two of its vertices. shew that the triangle formed by joining their centres is equal in all respects to the original triangle.

33 ABC is a triangle inscribed in a circle, and the bisectors of its angles which intersect at O are produced to meet the circumference in PQR shew that O is the orthocentre of the triangle PQR

34 Construct a triangle, having given a vertex, the orthocentre, and the centre of the circumscribed circle.

LocI

35. Given the base and vertical angle of a triangle, find the locus of its orthocentre.

Let BC be the given base, and X the given angle, and let BAC be any triangle on the base BC , having its vertical $\angle A$ equal to the $\angle X$

Draw the perp^s BE , CF , intersecting at the orthocentre O

It is required to find the locus of O .

Since the \angle 's OFA , OEA are rt. angles, the points O , F , A , E are coneycle, the $\angle FOE$ is the supplement of the $\angle A$,

the vert opp $\angle BOC$ is the supplement of the $\angle A$.

But the $\angle A$ is constant, being always equal to the $\angle X$, its supplement is constant;

that is, the ΔBOC has a fixed base, and constant vertical angle; hence the locus of its vertex O is the arc of a segment of which BC is the chord.

[See p. 187]

III 22.

36 Given the base and vertical angle of a triangle, find the locus of the intersection of the bisectors of its angles

Let BAC be any triangle on the given base BC , having its vertical angle equal to the given $\angle X$, and let AI , BI , CI be the bisectors of its angles [see Ex 2, p 103] it is required to find the locus of the point I

Denote the angles of the $\triangle ABC$ by A, B, C , and let the $\angle BIC$ be denoted by I . Then from the $\triangle BIC$,

(i) $I + \frac{1}{2}B + \frac{1}{2}C = \text{two rt angles}$, I 32
and from the $\triangle ABC$,

$A + B + C = \text{two rt angles}$, I 32

(ii) so that $\frac{1}{2}A + \frac{1}{2}B + \frac{1}{2}C = \text{one rt angle}$,
, taking the differences of the equals in (i) and (ii),

$I - \frac{1}{2}A = \text{one rt angle}$

or, $I = \text{one rt angle} + \frac{1}{2}A$

But A is constant, being always equal to the $\angle X$,

I is constant

, since the base BC is fixed, the locus of I is the arc of a segment of which BC is the chord

37 Given the base and vertical angle of a triangle, find the locus of the centroid, that is, the intersection of the medians

Let BAC be any triangle on the given base BC , having its vertical angle equal to the given angle S , let the medians AX , BY , CZ intersect at the centroid G [see Ex 4, p 105]

it is required to find the locus of the point G

Through G draw GP , GQ par^l to AB and AC respectively

Then ZG is a third part of ZC ,

Ex 4, p 105

and since GP is par^l to ZB ,

BP is a third part of BC .

Similarly QC is a third part of BC ,

P and Q are fixed points

Now since PG , GQ are par^l respectively to BA , AC ,

the $\angle PGQ = \text{the } \angle BAC$,

$= \text{the } \angle S$,

that is, the $\angle PGQ$ is constant,

and since the base PQ is fixed,

the locus of G is the arc of a segment of which PQ is the chord

Ex 19, p 99

Constr

I 29

Ob. In this problem the points A and G move on the arcs of similar segments.

38 Given the base and the vertical angle of a triangle; find the locus of the intersection of the bisectors of the exterior base angles

39 Through the extremities of a given straight line AB any two parallel straight lines AP, BQ are drawn; find the locus of the intersection of the bisectors of the angles PAB, QBA.

40 Find the locus of the middle points of chords of a circle drawn through a fixed point

Distinguish between the cases when the given point is within, on, or without the circumference

41 Find the locus of the points of contact of tangents drawn from a fixed point to a system of concentric circles

42 Find the locus of the intersection of straight lines which pass through two fixed points on a circle and intercept on its circumference an arc of constant length.

43 A and B are two fixed points on the circumference of a circle, and PQ is any diameter find the locus of the intersection of PA and QB

44 BAC is any triangle described on the fixed base BC and having a constant vertical angle, and BA is produced to P, so that BP is equal to the sum of the sides containing the vertical angle find the locus of P

45 AB is a fixed chord of a circle, and AC is a moveable chord passing through A if the parallelogram CB is completed, find the locus of the intersection of its diagonals

46 A straight rod PQ slides between two rulers placed at right angles to one another, and from its extremities PX, QX are drawn perpendicular to the rulers find the locus of X.

47 Two circles whose centres are C and D, intersect at A and B through A, any straight line PAQ is drawn terminated by the circumferences, and PC, QD intersect at X find the locus of X, and shew that it passes through B [Ex 9, p 216]

48 Two circles intersect at A and B, and through P, any point on the circumference of one of them, two straight lines PA, PB are drawn, and produced if necessary, to cut the other circle at X and Y. find the locus of the intersection of AY and BX

49 Two circles intersect at A and B, HAK is a fixed straight line drawn through A and terminated by the circumferences, and PAQ is any other straight line similarly drawn find the locus of the intersection of HP and QK [Ex 3, p 186]

50 Two segments of circles are on the same chord AB and on the same side of it, and P and Q are any points one on each arc find the locus of the intersection of the bisectors of the angles PAQ , PBQ

51 Two circles intersect at A and B , and through A any straight line PAQ is drawn terminated by the circumferences find the locus of the middle point of PQ

MISCELLANEOUS EXAMPLES ON ANGLES IN A CIRCLE.

52 ABC is a triangle, and circles are drawn through B, C , cutting the sides in P, Q, P', Q' , shew that $PQ, P'Q'$ are parallel to one another and to the tangent drawn at A to the circle circumscribed about the triangle

53 Two circles intersect at B and C , and from any point A , on the circumference of one of them, AB, AC are drawn, and produced if necessary, to meet the other at D and E shew that DE is parallel to the tangent at A

54 A secant PAB and a tangent PT are drawn to a circle from an external point P , and the bisector of the angle ATB meets AB at C shew that PC is equal to PT

55 From a point A on the circumference of a circle two chords AB, AC are drawn, and also the diameter AF if AB, AC are produced to meet the tangent at F in D and E , shew that the triangles ABC, AED are equiangular to one another

56 O is any point within a triangle ABC , and OD, OE, OF are drawn perpendicular to BC, CA, AB respectively shew that the angle BOC is equal to the sum of the angles BAC, EDF

57 If two tangents are drawn to a circle from an external point, shew that they contain an angle equal to the difference of the angles in the segments cut off by the chord of contact

58 Two circles intersect, and through a point of section a straight line is drawn bisecting the angle between the diameters through that point shew that this straight line cuts off similar segments from the two circles

59 Two equal circles intersect at A and B , and from centre A , with any radius less than AB a third circle is described cutting the given circles on the same side of AB at C and D shew that the points B, C, D are collinear

60 ABC and $A'B'C'$ are two triangles inscribed in a circle, so that AB, AC are respectively parallel to $A'B', A'C'$ shew that BC' is parallel to $B'C$.

61 Two circles intersect at A and B, and through A two straight lines HAK, PAQ are drawn terminated by the circumferences if HP and KQ intersect at X, shew that the points H, B, K, X are concyclic

62 Describe a circle touching a given straight line at a given point, so that tangents drawn to it from two fixed points in the given line may be parallel [See Ex 10, p 183]

63 C is the centre of a circle, and CA, CB two fixed radii if from any point P on the arc AB perpendiculars PX, PY are drawn to CA and CB, shew that the distance XY is constant

64 AB is a chord of a circle, and P any point in its circumference, PM is drawn perpendicular to AB, and AN is drawn perpendicular to the tangent at P shew that MN is parallel to PB

65 P is any point on the circumference of a circle of which AB is a fixed diameter, and PN is drawn perpendicular to AB; on AN and BN as diameters circles are described, which are cut by AP, BP at X and Y. shew that XY is a common tangent to these circles.

66 Upon the same chord and on the same side of it three segments of circles are described containing respectively a given angle, its supplement and a right angle. shew that the intercept made by the two former segments upon any straight line drawn through an extremity of the given chord is bisected by the latter segment

67 Two straight lines of indefinite length touch a given circle, and any chord is drawn so as to be bisected by the chord of contact; if the former chord is produced, shew that the intercepts between the circumference and the tangents are equal.

68 Two circles intersect one another through one of the points of contact draw a straight line of given length terminated by the circumferences

69 On the three sides of any triangle equilateral triangles are described remote from the given triangle shew that the circles described about them intersect at a point

70 On BC, CA, AB the sides of a triangle ABC, any points P, Q, R are taken, shew that the circles described about the triangles AQR, BRP, CPQ meet in a point

71 Find a point within a triangle at which the sides subtend equal angles.

72 Describe an equilateral triangle so that its sides may pass through three given points

73 Describe a triangle equal in all respects to a given triangle, and having its sides passing through three given points

SIMSON'S LINE

74 If from any point on the circumference of the circle circumscribed about a triangle, perpendiculars are drawn to the three sides, the feet of these perpendiculars are collinear

Let P be any point on the C^o of the circle circumscribed about the $\triangle ABC$, and let PD , PE , PF be the perp^s drawn from P to the three sides

It is required to prove that the points D , E , F are collinear

Join FD and DE

then FD and DE shall be in the same st line

Join PB , PC

Because the \angle^s PDB , PFB are rt angles,
the points P , D , B , F are concyclic

Hyp

the \angle PDF = the \angle PBF , in the same segment

III 21

But since $BACP$ is a quadⁱ inscribed in a circle, having one of its sides AB produced to F ,

the ext \angle PBF = the opp int \angle ACP Ex 3, p 183

the \angle PDF = the \angle ACP

To each add the \angle PDE

then the \angle^s PDF , PDE = the \angle^s ECP , PDE

But since the \angle^s PDC , PEC are rt angles,

the points P , D , E , C are concyclic,

the \angle^s ECP , PDE together = two rt angles

the \angle^s PDF , PDE together = two rt angles,

FD and DE are in the same st line,

I 14

that is, the points D , E , F are collinear

Q E D

[This theorem is attributed to Robert Simson, and accordingly the straight line FDE is sometimes spoken of as the Simson's Line of the triangle ABC for the point P some writers also call it the Pedal of the triangle ABC for the point P]

75 ABC is a triangle inscribed in a circle, and from any point P on the circumference PD , PF are drawn perpendicular to BC and AB if FD , or FD produced, cuts AC at E , shew that PE is perpendicular to AC

76 Find the locus of a point which moves so that if perpendiculars are drawn from it to the sides of a given triangle, their feet are collinear

77 ABC and $A'B'C'$ are two triangles having a common vertical angle, and the circles circumscribed about them meet again at P shew that the feet of perpendiculars drawn from P to the four lines AB , AC , BC , $B'C'$ are collinear

78 A triangle is inscribed in a circle, and any point P on the circumference is joined to the orthocentre of the triangle; shew that this joining line is bisected by the pedal of the point P

IV ON THE CIRCLE IN CONNECTION WITH RECTANGLES

See Propositions 35, 36, 37

1 If from any external point P two tangents are drawn to a given circle whose centre is O, and if OP meets the chord of contact at Q, then the rectangle OP, OQ is equal to the square on the radius

Let PH, PK be tangents, drawn from the external point P to the \odot HAK, whose centre is O, and let OP meet HK the chord of contact at Q, and the \odot at A: then shall the rect OP, OQ = the sq on OA

On HP as diameter describe a circle, this circle must pass through Q, since the \angle HQP is a rt angle

III 31

Join OH.

Then since PH is a tangent to the \odot HAK, the \angle OHP is a rt angle.

And since HP is a diameter of the \odot HQP,

\therefore OH touches the \odot HQP at H

\therefore the rect OP, OQ = the sq on OH,

= the sq. on OA

III 16.

III 36

Q E D.

2 ABC is a triangle, and AD, BE, CF the perpendiculars drawn from the vertices to the opposite sides, meeting in the orthocentre O shew that the rect AO, OD = the rect BO, OE = the rect. CO, OF.

3 ABC is a triangle, and AD, BE the perpendiculars drawn from A and B on the opposite sides. shew that the rectangle CA, CE is equal to the rectangle CB, CD.

4 ABC is a triangle right-angled at C, and from D, any point in the hypotenuse AB, a straight line DE is drawn perpendicular to AB and meeting BC at E. shew that the square on DE is equal to the difference of the rectangles AD, DB and CE, EB

5 From an external point P two tangents are drawn to a given circle whose centre is O, and OP meets the chord of contact at Q shew that any circle which passes through the points P, Q will cut the given circle orthogonally [See Def. p 222]

6 A series of circles pass through two given points, and from a fixed point in the common chord produced tangents are drawn to all the circles shew that the points of contact lie on a circle which cuts all the given circles orthogonally.

7 All circles which pass through a fixed point, and cut a given circle orthogonally, pass also through a second fixed point

8 Find the locus of the centres of all circles which pass through a given point and cut a given circle orthogonally

9 Describe a circle to pass through two given points and cut a given circle orthogonally

10 A, B, C, D are four points taken in order on a given straight line find a point O between B and C such that the rectangle OA, OB may be equal to the rectangle OC, OD.

11 AB is a fixed diameter of a circle, and CD a fixed straight line of indefinite length cutting AB or AB produced at right angles, any straight line is drawn through A to cut CD at P and the circle at Q shew that the rectangle AP, AQ is constant

12. AB is a fixed diameter of a circle, and CD a fixed chord at right angles to AB; any straight line is drawn through A to cut CD at P and the circle at Q shew that the rectangle AP, AQ is equal to the square on AC.

13 A is a fixed point and CD a fixed straight line of indefinite length, AP is any straight line drawn through A to meet CD at P, and in AP a point Q is taken such that the rectangle AP, AQ is constant find the locus of Q

14 Two circles intersect orthogonally, and tangents are drawn from any point on the circumference of one to touch the other prove that the first circle passes through the middle point of the chord of contact of the tangents [Ex 1, p 233]

15 A semicircle is described on AB as diameter, and any two chords AC, BD are drawn intersecting at P shew that

$$AB^2 = AC \cdot AP + BD \cdot BP$$

16. Two circles intersect at B and C, and the two direct common tangents AE and DF are drawn if the common chord is produced to meet the tangents at G and H, shew that $GH^2 = AE^2 + BC^2$

17 If from a point P, without a circle, PM is drawn perpendicular to a diameter AB, and also a secant PCD, shew that

$$PM^2 = PC \cdot PD \pm AM \cdot MB,$$

according as PM intersects the circle or not

18 Three circles intersect at D, and their other points of intersection are A, B, C, AD-cuts the circle BDC at E, and EB, EC cut the circles ADB, ADC respectively at F and G: shew that the points F, A, G are collinear.

19 A semicircle is described on a given diameter BC, and from B and C any two chords BE, CF are drawn intersecting within the semicircle at O, BF and CE are produced to meet at A shew that the sum of the squares on AB, AC is equal to twice the square on the tangent from A together with the square on BC.

20. X and Y are two fixed points in the diameter of a circle equidistant from the centre C through X any chord PXQ is drawn, and its extremities are joined to Y, shew that the sum of the squares on the sides of the triangle PYQ is constant [See p 147, Ex 24]

PROBLEMS ON TANGENCY

21 To describe a circle to pass through two given points and to touch a given straight line

Let A and B be the given points, and CD the given st line it is required to describe a circle to pass through A and B and to touch CD

Join BA, and produce it to meet CD at P

Describe a square equal to the rect PA, PB, and from PD (or PC) cut off PQ equal to a side of this square

Through A, B and Q describe a circle Ex 4, p 156
Then since the rect PA, PB = the sq on PQ,
the \odot ABQ touches CD at Q

III 37
Q E R

NOTE (1) Since PQ may be taken on either side of P, it is clear that there are in general two solutions of the problem

(11) When AB is parallel to the given line CD, the above method is not applicable In this case a simple construction follows from III 1, Cor and III 16; and it will be found that only one solution exists.

22 To describe a circle to pass through two given points and to touch a given circle

Let A and B be the given points, and CRP the given circle

it is required to describe a circle to pass through A and B, and to touch the $\odot CRP$

Through A and B describe any circle to cut the given circle at P and Q

Join AB, PQ, and produce them to meet at D

From D draw DC to touch the given circle, and let C be the point of contact

Then the circle described through A, B, C will touch the given circle

For, from the $\odot ABQP$ the rect DA, DB = the rect DP, DQ
and from the $\odot PQC$, the rect DP, DQ = the sq on DC, III 36
the rect DA, DB = the sq on DC

DC touches the $\odot ABC$ at C

III 37

But DC touches the $\odot PQC$ at C,
the $\odot ABC$ touches the given circle, and it passes through the given points A and B

Constr

Q.E.F.

NOTE (i) Since two tangents may be drawn from D to the given circle, it follows that there will be two solutions of the problem

(ii) The general construction fails when the straight line bisecting AB at right angles passes through the centre of the given circle the problem then becomes symmetrical, and the solution is obvious.

23 To describe a circle to pass through a given point and to touch two given straight lines

Let P be the given point, and AB, AC the given straight lines
it is required to describe a circle to pass through P and to touch AB, AC

Now the centre of every circle which touches AB and AC must lie on the bisector of the $\angle BAC$

Ex. 7, p 183

Hence draw AE bisecting the $\angle BAC$

From P draw PK perp to AE, and produce it to P', making KP' equal to PK

Then every circle which has its centre in AE , and passes through P , must also pass through P' Ex 1, p 215

Hence the problem is now reduced to drawing a circle through P and P' to touch either AC or AB Ex 21, p 235.

Produce $P'P$ to meet AC at S

Describe a square equal to the rect SP, SP' , II. 1

and cut off SR equal to a side of the square

Describe a circle through the points P', P, R .

then since the rect $SP, SP' =$ the sq. on SR , Const

the circle touches AC at R ; III 37

and since its centre is in AE , the bisector of the $\angle BAC$,

it may be shewn also to touch AB Q F F

NOTE (i) Since SR may be taken on either side of S , it follows that there will be two solutions of the problem

(ii) If the given straight lines are parallel, the centre lies on the parallel straight line mid-way between them, and the construction proceeds as before

24 To describe a circle to touch two given straight lines and a given circle

Let AB, AC be the two given st. lines, and D the centre of the given circle

it is required to describe a circle to touch AB, AC and the circle whose centre is D

Draw EF, GH par^l to AB and AC respectively, on the sides remote from D , and at distances from them equal to the radius of the given circle

Describe the $\odot MND$ to touch EF and GH at M and N , and to pass through D Ex. 23, p 236.

Let O be the centre of this circle.

Join OM, ON, OD meeting AB, AC and the given circle at P, Q and R

Then a circle described from centre O with radius OP will touch AB, AC and the given circle.

For since O is the centre of the $\odot MND$,

$$OM = ON = OD.$$

$$\text{But } PM = QN = RD;$$

$$\therefore OP = OQ = OR.$$

Constr

\therefore a circle described from centre O , with radius OP , will pass through Q and R

And since the \angle^s at M and N are rt angles,

the \angle^s at P and Q are rt angles,

\therefore the $\odot PQR$ touches AB and AC .

III. 18

I. 20.

And since R, the point in which the circles meet, is on the line of centres OD,

the \odot PQR touches the given circle

Q E F

NOTE There will be two solutions of this problem, since two circles may be drawn to touch EF, GH and to pass through D

25 To describe a circle to pass through a given point and touch a given straight line and a given circle

Let P be the given point, AB the given st line, and DHE the given circle, of which C is the centre
it is required to describe a circle to pass through P, and to touch AB and the \odot DHE

Through C draw DGEF perp to AB, cutting the circle at the points D and E, of which E is between C and AB

Join DP,
and by describing a circle through F, E, and P, find a point K in DP (or DP produced) such that the rect DE, DF = the rect DK, DP

Describe a circle to pass through P, K and touch AB Ex 21, p 233
This circle shall also touch the given \odot DHE

For let G be the point at which this circle touches AB
Join DG, cutting the given circle DHE at H

Join HE

Then the \angle DHE is a rt angle, being in a semicircle
also the angle at F is a rt angle,
the points E, F, G, H are concyclic
the rect DE, DF = the rect DH, DG
but the rect DE, DF = the rect DK, DP
the rect DH, DG = the rect DK, DP
the point H is on the \odot PKG

III 31
Const

III 36
Constr.

Let O be the centre of the \odot PHG

Join OG, OH, CH

Then OG and DF are par^l, since they are both perp to AB,
and DG meets them

the \angle OGD = the \angle GDC

I 29

But since OG = OH, and CD = CH,

the \angle OGH = the \angle OHG, and the \angle CDH = the \angle CHD
the \angle OHG = the \angle CHD,

OH and CH are in one st line

the \odot PHG touches the given \odot DHE.

Q. E. F

NOTE (i) Since two circles may be drawn to pass through P, K and to touch AB, it follows that there will be two solutions of the present problem

(ii) Two more solutions may be obtained by joining PE, and proceeding as before

The student should examine the nature of the contact between the circles in each case.

26 Describe a circle to pass through a given point, to touch a given straight line, and to have its centre on another given straight line

27 Describe a circle to pass through a given point, to touch a given circle, and to have its centre on a given straight line

28 Describe a circle to pass through two given points, and to intercept an arc of given length on a given circle

29 Describe a circle to touch a given circle and a given straight line at a given point

30 Describe a circle to touch two given circles and a given straight line

V ON MAXIMA AND MINIMA

We gather from the Theory of Loci that the position of an angle, line or figure is capable under suitable conditions of gradual change, and it is usually found that change of *position* involves a corresponding and gradual change of *magnitude*.

Under these circumstances we may be required to note if any situations exist at which the magnitude in question, after increasing, begins to decrease, or after decreasing, to increase in such situations the Magnitude is said to have reached a **Maximum** or a **Minimum** value, for in the former case it is greater, and in the latter case less than in adjacent situations on either side. In the geometry of the circle and straight line we only meet with such cases of continuous change as admit of one transition from an increasing to a decreasing state—or vice versa—so that in all the problems with which we have to deal (where a single circle is involved) there can be only one Maximum and one Minimum—the Maximum being the greatest, and the Minimum being the least value that the variable magnitude is capable of taking

Thus a variable geometrical magnitude reaches its maximum or minimum value at a *turning point*, towards which the magnitude may mount or descend from either side it is natural therefore to expect a maximum or minimum value to occur when, in the course of its change, the magnitude assumes a *symmetrical* form or position, and this is usually found to be the case.

This general connection between a symmetrical form or position and a maximum or minimum value is not exact enough to constitute a *proof* in any particular problem, but by means of it a situation is suggested, which on further examination may be shewn to give the maximum or minimum value sought for

For example, suppose it is required
to determine the greatest straight line that may be drawn perpendicular to the chord of a segment of a circle and intercepted between the chord and the arc

we immediately anticipate that the greatest perpendicular is that which occupies a *symmetrical* position in the figure, namely the perpendicular which passes through the middle point of the chord, and on further examination this may be proved to be the case by means of I 19, and I 34.

Again we are able to find at what point a geometrical magnitude, varying under certain conditions, assumes its Maximum or Minimum value, if we can discover a construction for drawing the magnitude so that it may have an *assigned* value for we may then examine between what limits the assigned value must lie in order that the construction may be possible, and the higher or lower limit will give the Maximum or Minimum sought for

It was pointed out in the chapter on the Intersection of Loci, [see page 119] that if under certain conditions existing among the data, *two* solutions of a problem are possible, and under other conditions, *no* solution exists, there will always be some intermediate condition under which *one* and *only one* distinct solution is possible

Under these circumstances this single or limiting solution will always be found to correspond to the maximum or minimum value of the magnitude to be constructed

1 For example, suppose it is required
to divide a given straight line so that the rectangle contained by the two segments may be a maximum

We may first attempt to divide the given straight line so that the rectangle contained by its segments may have a *given* area—that is, be equal to the square on a given straight line.

Let AB be the given straight line, and K the s.d. of the given square:

it is required to divide the st line AB at a point M , so that the rect AM, MB may be equal to the sq on K

Adopting a construction suggested by π . 14,

describe a semicircle on AB , and at any point X in AB , or AB produced, draw XY perp to AB , and equal to K

Through Y draw YZ par^l to AB , to meet the arc of the semicircle at P .

Then if the perp PM is drawn to AB , it may be shewn after the manner of π 14, or by ix . 35 that

$$\begin{aligned} \text{the rect } AM, MB &= \text{the sq on } PM. \\ &= \text{the sq on } K \end{aligned}$$

So that the rectangle AM, MB increases as K increases

Now if K is less than the radius CD , then YZ will meet the arc of the semicircle in two points P, P' , and it follows that AB may be divided at *two* points, so that the rectangle contained by its segments may be equal to the square on K . If K increases, the st line YZ will recede from AB , and the points of intersection P, P' will continually approach one another, until, when K is equal to the radius CD , the st line YZ (now in the position $Y'Z'$) will meet the arc in *two coincident points*, that is, will touch the semicircle at D , and there will be only *one* solution of the problem

If K is greater than CD , the straight line YZ will not meet the semicircle, and the problem is impossible

Hence the greatest length that K may have, in order that the construction may be possible, is the radius CD

the rect. AM, MB is a maximum, when it is equal to the square on CD ,

that is, when PM coincides with DC , and consequently when M is the middle point of AB

Obs The special feature to be noticed in this problem is that the maximum is found at the transitional point between *two* solutions and *no* solution; that is, when the two solutions coincide and become identical

The following example illustrates the same point

2 To find at what point in a given straight line the angle subtended by the line joining two given points, which are on the same side of the given straight line, is a maximum

Let CD be the given st line, and A, B the given points on the same side of CD

it is required to find at what point in CD the angle subtended by the st line AB is a maximum

First determine at what point in CD , the st line AB subtends a given angle

This is done as follows —

On AB describe a segment of a circle containing an angle equal to the given angle III 33

If the arc of this segment intersects CD , two points in CD are found at which AB subtends the given angle but if the arc does not meet CD , no solution is given

In accordance with the principles explained above, we expect that a maximum angle is determined at the limiting position, that is, when the arc touches CD , or meets it at two coincident points

[See page 213]

This we may prove to be the case

Describe a circle to pass through A and B , and to touch the st line CD

[Ex 21, p 235]

Let P be the point of contact

Then shall the $\angle APB$ be greater than any other angle subtended by AB at a point in CD on the same side of AB as P .

For take Q , any other point in CD , on the same side of AB as P ,

and join AQ, QB

Since Q is a point in the tangent other than the point of contact, it must be without the circle,

either BQ or AQ must meet the arc of the segment APB

Let BQ meet the arc at K join AK .

Then the $\angle APB = \angle AKB$, in the same segment
but the ext $\angle AKB$ is greater than the int opp $\angle AQB$
the $\angle APB$ is greater than $\angle AQB$

Similarly the $\angle APB$ may be shewn to be greater than any other angle subtended by AB at a point in CD on the same side of AB

that is, the $\angle APB$ is the greatest of all such angles Q.E.D.

NOTE Two circles may be described to pass through A and B , and to touch CD , the points of contact being on opposite sides of AB

hence two points in CD may be found such that the angle subtended by AB at each of them is greater than the angle subtended at any other point in CD on the same side of AB

We add two more examples of considerable importance

3 In a straight line of indefinite length find a point such that the sum of its distances from two given points, on the same side of the given line, shall be a minimum.

Let CD be the given st line of indefinite length, and A, B the given points on the same side of CD
it is required to find a point P in CD such that the sum of AP, PB is a minimum

Draw AF perp to CD ,
and produce AF to E , making FE equal to AF

Join EB , cutting CD at P .

Join AP, PB

Then of all lines drawn from A and B to a point in CD ,

the sum of AP, PB shall be the least

For, let Q be any other point in CD

Join AQ, BQ, EQ

Now in the $\Delta AFP, EFP$,

Because $\begin{cases} AF=EF, \\ \text{and } FP \text{ is common,} \\ \text{and the } \angle AFP = \text{the } \angle EFP, \text{ being rt angles} \end{cases}$ Constr

$AP=EP$. 1 4

Similarly it may be shewn that

$AQ=EQ$

Now in the ΔEQB , the two sides EQ, QB are together greater than EB ,

hence, AQ, QB are together greater than EB ,
that is, greater than AP, PB

Similarly the sum of the st lines drawn from A and B to any other point in CD may be shewn to be greater than AP, PB .

∴ the sum of AP, PB is a minimum

Q E D.

NOTE It follows from the above proof that

the $\angle APF = \text{the } \angle EPF$
 $= \text{the } \angle BPD$.

1 4

1 15

Thus the sum of AP, PB is a minimum, when these lines are equally inclined to CD .

4 Given two intersecting straight lines AB, AC, and a point P between them, shew that of all straight lines which pass through P and are terminated by AB, AC, that which is bisected at P cuts off the triangle of minimum area

Let EF be the st line, terminated by AB, AC, which is bisected at P
then the \triangle FAE shall be of minimum area

For let HK be any other st line passing through P
through E draw EM par^l to AC

Then in the \triangle 's HPF, MPE,

Because {	the \angle HPF = the \angle MPE,	1 15
	and the \angle HFP = the \angle MEP,	1 29
	and FP = EP,	Hyp
	the \triangle HPF = the \triangle MPE	1 26, Cor

But the \triangle MPE is less than the \triangle KPE,
the \triangle HPF is less than the \triangle KPE
to each add the fig AHPE,
then the \triangle FAE is less than the \triangle HAK

Similarly it may be shewn that the \triangle FAE is less than any other triangle formed by drawing a st line through P
that is, the \triangle FAE is a minimum

EXAMPLES

1 Two sides of a triangle are given in length, how must they be placed in order that the area of the triangle may be a maximum?

2 Of all triangles of given base and area, the isosceles is that which has the least perimeter

3 Given the base and vertical angle of a triangle, construct it so that its area may be a maximum

4 Find a point in a given straight line such that the tangents drawn from it to a given circle contain the greatest angle possible

5 A straight rod slips between two straight rulers placed at right angles to one another, in what position is the triangle intercepted between the rulers and rod a maximum?

6 Divide a given straight line into two parts, so that the sum of the squares on the segments may

- (i) be equal to a given square,
- (ii) may be a minimum.

7. Through a point of intersection of two circles draw a straight line terminated by the circumferences,

- (i) so that it may be of given length,
- (ii) so that it may be a maximum.

8. Two tangents to a circle cut one another at right angles; find the point on the intercepted arc such that the sum of the perpendiculars drawn from it to the tangents may be a minimum.

9. Straight lines are drawn from two given points to meet one another on the circumference of a given circle: prove that their sum is a minimum when they make equal angles with the tangent at the point of intersection

10. Of all triangles of given vertical angle and altitude, the isosceles is that which has the least area.

11 Two straight lines CA, CB of indefinite length are drawn from the centre of a circle to meet the circumference at A and B; then of all tangents that may be drawn to the circle at points on the arc AB, that whose intercept is bisected at the point of contact cuts off the triangle of minimum area

12 Given two intersecting tangents to a circle, draw a tangent to the convex arc so that the triangle formed by it and the given tangents may be of maximum area.

13 Of all triangles of given base and area, the isosceles is that which has the greatest vertical angle

14 Find a point on the circumference of a circle at which the straight line joining two given points (of which both are within, or both without the circle) subtends the greatest angle.

15 A bridge consists of three arches, whose spans are 40 ft., 32 ft and 40 ft respectively: shew that the point on either bank of the river at which the middle arch subtends the greatest angle is 63 feet distant from the bridge

16 From a given point P without a circle whose centre is C, draw a straight line to cut the circumference at A and B, so that the triangle ACB may be of maximum area.

17. Shew that the greatest rectangle which can be inscribed in a circle is a square

18 A and B are two fixed points without a circle: find a point P on the circumference such that the sum of the squares on AP, PB may be a minimum. [See p. 147, Ex. 21.]

19 A segment of a circle is described on the chord AB find a point P on its arc so that the sum of AP, BP may be a maximum

20 Of all triangles that can be inscribed in a circle that which has the greatest perimeter is equilateral

21 Of all triangles that can be inscribed in a given circle that which has the greatest area is equilateral

22 Of all triangles that can be inscribed in a given triangle that which has the least perimeter is the triangle formed by joining the feet of the perpendiculars drawn from the vertices on opposite sides

23 Of all rectangles of given area, the square has the least perimeter

24 Describe the triangle of maximum area, having its angles equal to those of a given triangle, and its sides passing through three given points

VI HARDER MISCELLANEOUS EXAMPLES

1 AB is a diameter of a given circle, and AC, BD, two chords on the same side of AB, intersect at E shew that the circle which passes through D, E, C cuts the given circle orthogonally

2 Two circles whose centres are C and D intersect at A and B, and a straight line PAQ is drawn through A and terminated by the circumferences prove that

(i) the angle PBQ = the angle CAD

(ii) the angle BPC = the angle BQD

3 Two chords AB, CD of a circle whose centre is O intersect at right angles at P shew that

(i) $PA^2 + PB^2 + PC^2 + PD^2 = 4 (\text{radius})^2$

(ii) $AB^2 + CD^2 + 4OP^2 = 8 (\text{radius})^2$

4 Two parallel tangents to a circle intercept on any third tangent a portion which is so divided at its point of contact that the rectangle contained by its two parts is equal to the square on the radius

5 Two equal circles move between two straight lines placed at right angles, so that each straight line is touched by one circle, and the two circles touch one another find the locus of the point of contact

6 AB is a given diameter of a circle, and CD is any parallel chord if any point X in AB is joined to the extremities of CD, shew that

$$XC^2 + XD^2 = XA^2 + XB^2$$

7. PQ is a fixed chord in a circle, and PX, QY any two parallel chords through A and B shew that XY touches a fixed concentric circle.

8 Two equal circles intersect at A and B, and from C any point on the circumference of one of them a perpendicular is drawn to AB, meeting the other circle at O and O' shew that either O or O' is the orthocentre of the triangle ABC. Distinguish between the two cases.

9 Three equal circles pass through the same point A, and their other points of intersection are B, C, D shew that of the four points A, B, C, D, each is the orthocentre of the triangle formed by joining the other three

10 From a given point without a circle draw a straight line to the concave circumference so as to be bisected by the convex circumference When is this problem impossible?

11 Draw a straight line cutting two concentric circles so that the chord intercepted by the circumference of the greater circle may be double of the chord intercepted by the less

12. ABC is a triangle inscribed in a circle, and A', B', C' are the middle points of the arcs subtended by the sides (remote from the opposite vertices) find the relation between the angles of the two triangles ABC, A'B'C', and prove that the pedal triangle of A'B'C' is equiangular to the triangle ABC

13. The opposite sides of a quadrilateral inscribed in a circle are produced to meet shew that the bisectors of the two angles so formed are perpendicular to one another

14 If a quadrilateral can have one circle inscribed in it, and another circumscribed about it, shew that the straight lines joining the opposite points of contact of the inscribed circle are perpendicular to one another.

15. Given the base of a triangle and the sum of the remaining sides, find the locus of the foot of the perpendicular from one extremity of the base on the bisector of the exterior vertical angle.

16. Two circles touch each other at C, and straight lines are drawn through C at right angles to one another, meeting the circles at P, P' and Q, Q' respectively. if the straight line which joins the centres is terminated by the circumferences at A and A', shew that

$$P'P^2 + Q'Q^2 = A'A^2.$$

17 Two circles cut one another orthogonally at A and B; P is any point on the arc of one circle intercepted by the other, and PA, PB are produced to meet the circumference of the second circle at C and D shew that CD is a diameter

18 ABC is a triangle, and from any point P perpendiculars PD , PE , PF are drawn to the sides if S_1 , S_2 , S_3 are the centres of the circles circumscribed about the triangles DPE , EPF , FPD , shew that the triangle $S_1S_2S_3$ is equiangular to the triangle ABC , and that the sides of the one are respectively half of the sides of the other.

19 Two tangents PA , PB are drawn from an external point P to a given circle, and C is the middle point of the chord of contact AB if XY is any chord through P , shew that AB bisects the angle XCX

20 Given the sum of two straight lines and the rectangle contained by them (equal to a given square) find the lines

21 Given the sum of the squares on two straight lines and the rectangle contained by them find the lines

22 Given the sum of two straight lines and the sum of the squares on them find the lines.

23 Given the difference between two straight lines, and the rectangle contained by them find the lines

24 Given the difference between two straight lines and the difference of their squares find the lines

25 ABC is a triangle, and the internal and external bisectors of the angle A meet BC , and BC produced, at P and P' if O is the middle point of PP' , shew that OA is a tangent to the circle circumscribed about the triangle ABC

26 ABC is a triangle, and from P , any point on the circumference of the circle circumscribed about it, perpendiculars are drawn to the sides BC , CA , AB meeting the circle again in A' , B' , C' , prove that

(i) the triangle $A'B'C'$ is identically equal to the triangle ABC

(ii) AA' , BB' , CC' are parallel.

27 Two equal circles intersect at fixed points A and B , and from any point in AB a perpendicular is drawn to meet the circumferences on the same side of AB at P and Q shew that PQ is of constant length

28 The straight lines which join the vertices of a triangle to the centre of its circumscribed circle, are perpendicular respectively to the sides of the pedal triangle

29 P is any point on the circumference of a circle circumscribed about a triangle ABC , and perpendiculars PD , PE are drawn from P to the sides BC , CA Find the locus of the centre of the circle circumscribed about the triangle PDE

30 P is any point on the circumference of a circle circumscribed about a triangle ABC: shew that the angle between Simson's Line for the point P and the side BC, is equal to the angle between AP and the diameter of the circumscribed circle.

31 Shew that the orthocentres of the four triangles formed by two pairs of intersecting straight lines are collinear.

32 Shew that the circles circumscribed about the four triangles formed by two pairs of intersecting straight lines meet in a point.

ON THE CONSTRUCTION OF TRIANGLES

33 Given the vertical angle, one of the sides containing it, and the length of the perpendicular from the vertex on the base: construct the triangle

34 Given the feet of the perpendiculars drawn from the vertices on the opposite sides: construct the triangle

35 Given the base, the altitude, and the radius of the circumscribed circle: construct the triangle

36 Given the base, the vertical angle, and the sum of the squares on the sides containing the vertical angle: construct the triangle

37 Given the base, the altitude and the sum of the squares on the sides containing the vertical angle: construct the triangle

38 Given the base, the vertical angle, and the difference of the squares on the sides containing the vertical angle: construct the triangle

39 Given the vertical angle, and the lengths of the two medians drawn from the extremities of the base: construct the triangle

40 Given the base, the vertical angle, and the difference of the angles at the base: construct the triangle.

41 Given the base, and the position of the bisector of the vertical angle: construct the triangle

42 Given the base, the vertical angle, and the length of the bisector of the vertical angle: construct the triangle

43 Given the perpendicular from the vertex on the base, the bisector of the vertical angle, and the median which bisects the base: construct the triangle

44. Given the bisector of the vertical angle, the median bisecting the base, and the difference of the angles at the base: construct the triangle

BOOK IV

Book IV consists entirely of problems, dealing with various rectilinear figures in relation to the circles which pass through their angular points, or are touched by their sides

DEFINITIONS

1 A Polygon is a rectilinear figure bounded by more than four sides

A Polygon of	<i>five</i> sides	is called a	Pentagon,
„	<i>six</i> sides	„	Hexagon,
„	<i>seven</i> sides	„	Heptagon,
„	<i>eight</i> sides	„	Octagon,
„	<i>ten</i> sides	„	Decagon,
„	<i>twelve</i> sides	„	Dodecagon,
„	<i>fifteen</i> sides	„	Quindecagon

2 A Polygon is Regular when all its sides are equal, and all its angles are equal

3 A rectilinear figure is said to be inscribed in a circle, when all its angular points are on the circumference of the circle and a circle is said to be circumscribed about a rectilinear figure, when the circumference of the circle passes through all the angular points of the figure

4 A rectilinear figure is said to be circumscribed about a circle, when each side of the figure is a tangent to the circle and a circle is said to be inscribed in a rectilinear figure, when the circumference of the circle is touched by each side of the figure

5 A straight line is said to be placed in a circle, when its extremities are on the circumference of the circle

PROPOSITION 1 PROBLEM

In a given circle to place a chord equal to a given straight line, which is not greater than the diameter of the circle

Let ABC be the given circle, and D the given straight line not greater than the diameter of the circle.

it is required to place in the $\odot ABC$ a chord equal to D

Draw CB, a diameter of the $\odot ABC$

Then if $CB = D$, the thing required is done

But if not, CB must be greater than D *Hyp.*

From CB cut off CE equal to D 1. 3

and from centre C, with radius CE, describe the $\odot AEF$,
cutting the given circle at A

Join CA

Then CA shall be the chord required

For $CA = CE$, being radii of the $\odot AEF$

and $CE = D$

$CA = D$

Constr

Q E F

EXERCISES

1 In a given circle place a chord of given length so as to pass through a given point (1) without, (2) within the circle

When is this problem impossible?

2 In a given circle place a chord of given length so that it may be parallel to a given straight line.

PROPOSITION 2 PROBLEM

In a given circle to inscribe a triangle equiangular to a given triangle.

Let ABC be the given circle, and DEF the given triangle. it is required to inscribe in the $\odot ABC$ a triangle equiangular to the $\triangle DEF$

At any point A , on the \odot^{ce} of the $\odot ABC$, draw the tangent GAH III 17

At A make the $\angle GAB$ equal to the $\angle DFE$; I 23

and make the $\angle HAC$ equal to the $\angle DEF$ I 23

Join BC

Then ABC shall be the triangle required

Because GH is a tangent to the $\odot ABC$, and from A its point of contact the chord AB is drawn,

the $\angle GAB =$ the $\angle ACB$ in the alt. segment III 32

. the $\angle ACB =$ the $\angle DFE$ Constr

Similarly the $\angle HAC =$ the $\angle ABC$, in the alt segment

the $\angle ABC =$ the $\angle DEF$ Constr

Hence the third $\angle BAC =$ the third $\angle EDF$,
for the three angles in each triangle are together equal to two rt angles I 32

. the $\triangle ABC$ is equiangular to the $\triangle DEF$, and it is inscribed in the $\odot ABC$.

PROPOSITION 3 PROBLEM

About a given circle to circumscribe a triangle equiangular to a given triangle

Let ABC be the given circle, and DEF the given Δ . it is required to circumscribe about the $\odot ABC$ a triangle equiangular to the ΔDEF .

Produce EF both ways to G and H

Find K the centre of the $\odot ABC$, III 1.
and draw any radius KB

At K make the $\angle BKA$ equal to the $\angle DEG$, I 23
and make the $\angle BKC$ equal to the $\angle DFH$

Through A, B, C draw LM, MN, NL perp to KA, KB, KC
Then LMN shall be the triangle required

Because LM, MN, NL are drawn perp to radii at their extremities,

LM, MN, NL are tangents to the circle III 16.

And because the four angles of the quadrilateral $AKBM$ together = four rt angles, I 32 Cor

and of these, the $\angle^s KAM, KBM$, are rt angles, Constr
the $\angle^s AKB, AMB$, together = two rt angles

But the $\angle^s DEG, DEF$ together = two rt angles, I 13
the $\angle^s AKB, AMB$ = the $\angle^s DEG, DEF$;

and of these, the $\angle AKB$ = the $\angle DEG$, Constr
the $\angle AMB$ = the $\angle DEF$.

Similarly it may be shewn that the $\angle LNM$ = the $\angle DFE$
the third $\angle MLN$ = the third $\angle EDF$. I 32

. the ΔLMN is equiangular to the ΔDEF , and it is circumscribed about the $\odot ABC$. Q E F.

PROPOSITION 4 PROBLEM

To inscribe a circle in a given triangle

Let ABC be the given triangle
it is required to inscribe a circle in the $\triangle ABC$

Bisect the $\angle^s ABC, ACB$ by the st lines BI, CI , which intersect at I I 9

From I draw IE, IF, IG perp to AB, BC, CA I 12

Then in the $\triangle^s EIB, FIB$,

Because { the $\angle EBI = \text{the } \angle FBI$, Constr
and the $\angle BEI = \text{the } \angle BFI$, being rt angles,
and BI is common,
 $IE = IF$ I 26

Similarly it may be shewn that $IF = IG$

IE, IF, IG are all equal

From centre I , with radius IE , describe a circle
this circle must pass through the points E, F, G ,
and it will be inscribed in the $\triangle ABC$

For since IE, IF, IG are radn of the $\bigcirc EFG$,
and since the \angle^s at E, F, G are rt. angles,
the $\bigcirc EFG$ is touched at these points by AB, BC, CA

the $\bigcirc EFG$ is inscribed in the $\triangle ABC$ III 16

Q E F

NOTE From page 103 it is seen that if AI be joined, then AI bisects the angle BAC

Hence it follows that the bisectors of the angles of a triangle are concurrent, the point of intersection being the centre of the inscribed circle

The centre of the circle inscribed in a triangle is sometimes called its **in-centre**

DEFINITION.

A circle which touches one side of a triangle and the other two sides produced is said to be an **escribed circle** of the triangle

To draw an escribed circle of a given triangle

Let ABC be the given triangle, of which the two sides AB , AC are produced to E and F

it is required to describe a circle touching BC , and AB , AC produced

Bisect the $\angle^s CBE$, BCF by the st lines BI_1 , CI_1 , which intersect at I_1 1 9

From I_1 draw I_1G , I_1H , I_1K perp. to AE , BC , AF 1 12

Then in the $\Delta^s I_1BG$, I_1BH ,
 Because $\left\{ \begin{array}{l} \text{the } \angle I_1BG = \text{the } \angle I_1BH, \text{ Constr} \\ \text{and the } \angle I_1GB = \text{the } \angle I_1HB, \\ \text{being rt angles,} \\ \text{also } I_1B \text{ is common,} \\ I_1G = I_1H \end{array} \right.$

Similarly it may be shewn that $I_1H = I_1K$;

I_1G , I_1H , I_1K are all equal.

From centre I_1 with radius I_1G , describe a circle

this circle must pass through the points G , H , K
 and it will be an escribed circle of the ΔABC

For since I_1H , I_1G , I_1K are radii of the $\circ HGK$,

and since the angles at H , G , K are rt angles,
 the $\circ GHK$ is touched at these points by BC , and by AB , AC produced

the $\circ GHK$ is an escribed circle of the ΔABC Q.E.F.

It is clear that every triangle has *three* escribed circles

NOTE From page 104 it is seen that if AI_1 be joined, then AI_1 bisects the angle BAC hence it follows that

The bisectors of two exterior angles of a triangle and the bisector of the third angle are concurrent, the point of intersection being the centre of an escribed circle

PROPOSITION 5. PROBLEM

To circumscribe a circle about a given triangle

Let ABC be the given triangle.

it is required to circumscribe a circle about the $\triangle ABC$

Draw DS bisecting AB at rt angles, I 11.

and draw ES bisecting AC at rt angles,

then since AB, AC are neither par^l, nor in the same st line,

DS and ES must meet at some point S

Join SA ,

and if S be not in BC , join SB, SC

Then in the $\triangle^s ADS, BDS$,

$AD = BD$

Because { and DS is common to both ;
(and the $\angle ADS =$ the $\angle BDS$, being rt angles ,
 $SA = SB$

Similarly it may be shewn that $SC = SA$

SA, SB, SC are all equal

From centre S , with radius SA , describe a circle
this circle must pass through the points A, B, C , and is
therefore circumscribed about the $\triangle ABC$ Q E F

It follows that

(1) when the centre of the circumscribed circle falls *within* the triangle, each of its angles must be acute, for each angle is then in a segment greater than a semicircle -

(2) when the centre falls on *one of the sides* of the triangle, the angle opposite to this side must be a right angle, for it is the angle in a semicircle.

(iii) when the centre falls *without* the triangle, the angle opposite to the side beyond which the centre falls, must be obtuse, for it is the angle in a segment less than a semicircle.

Therefore, conversely, if the given triangle be acute-angled, the centre of the circumscribed circle falls within it: if it be a right-angled triangle, the centre falls on the hypotenuse: if it be an obtuse-angled triangle, the centre falls without the triangle.

NOTE. From page 103 it is seen that if S be joined to the middle point of BC , then the joining line is perpendicular to BC .

Hence the perpendiculars drawn to the sides of a triangle from their middle points are concurrent, the point of intersection being the centre of the circle circumscribed about the triangle

The centre of the circle circumscribed about a triangle is sometimes called its *circum-centre*.

EXERCISES

ON THE INSCRIBED, CIRCUMSCRIBED, AND ESCRIBED CIRCLES OF A TRIANGLE.

1. An equilateral triangle is inscribed in a circle, and tangents are drawn at its vertices, prove that

- (i) the resulting figure is an equilateral triangle
- (ii) its area is four times that of the given triangle.

2. Describe a circle to touch two parallel straight lines and a third straight line which meets them. Shew that two such circles can be drawn, and that they are equal

3. *Triangles which have equal bases and equal vertical angles have equal circumscribed circles.*

4. I is the centre of the circle inscribed in the triangle ABC , and I_1 is the centre of the circle which touches BC and AB, AC produced: shew that A, I, I_1 are collinear.

5. If the inscribed and circumscribed circles of a triangle are concentric, shew that the triangle is equilateral, and that the diameter of the circumscribed circle is double that of the inscribed circle.

6. ABC is a triangle, and I, S are the centres of the inscribed and circumscribed circles; if A, I, S are collinear, shew that $AB = AC$

7. The sum of the diameters of the inscribed and circumscribed circles of a right-angled triangle is equal to the sum of the sides containing the right angle

8. If the circle inscribed in a triangle ABC touches the sides at D, E, F , shew that the triangle DEF is acute-angled, and express its angles in terms of the angles at A, B, C

9. If I is the centre of the circle inscribed in the triangle ABC , and I_1 the centre of the escribed circle which touches BC , shew that I, B, I_1, C are concyclic

10. In any triangle the difference of two sides is equal to the difference of the segments into which the third side is divided at the point of contact of the inscribed circle

11. In the triangle ABC the bisector of the angle BAC meets the base at D , and from I the centre of the inscribed circle a perpendicular IE is drawn to BC shew that the angle BID is equal to the angle CIE

12. In the triangle ABC , I and S are the centres of the inscribed and circumscribed circles shew that IS subtends at A an angle equal to half the difference of the angles at the base of the triangle

13. In a triangle ABC , I and S are the centres of the inscribed and circumscribed circles, and AD is drawn perpendicular to BC shew that AI is the bisector of the angle DAS

14. Shew that the area of a triangle is equal to the rectangle contained by its semi perimeter and the radius of the inscribed circle

15. The diagonals of a quadrilateral $ABCD$ intersect at O shew that the centres of the circles circumscribed about the four triangles AOB, BOC, COD, DOA are at the angular points of a parallelogram

16. In any triangle ABC , if I is the centre of the inscribed circle, and if AI is produced to meet the circumscribed circle at O , shew that O is the centre of the circle circumscribed about the triangle BIC

17. Given the base, altitude, and the radius of the circumscribed circle, construct the triangle

18. Describe a circle to intercept equal chords of given length on three given straight lines

19. In an equilateral triangle the radii of the circumscribed and escribed circles are respectively double and treble of the radius of the inscribed circle

20. Two circles whose centres are A, B, C touch one another externally two by two at D, E, F shew that the inscribed circle of the triangle ABC is the circumscribed circle of the triangle DEF

PROPOSITION 6 PROBLEM

To inscribe a square in a given circle.

Let ABCD be the given circle.
it is required to inscribe a square in the \odot ABCD

Find E the centre of the circle : III. 1.
and draw two diameters AC, BD perp to one another I. 11.
Join AB, BC, CD, DA.

Then the fig ABCD shall be the square required.

For in the \triangle BEA, DEA,
Because $\left\{ \begin{array}{l} BE = DE, \\ \text{and EA is common,} \\ \text{and the } \angle BEA = \text{the } \angle DEA, \text{ being rt angles,} \end{array} \right.$
BA = DA I. 4.

Similarly it may be shewn that CD = DA, and that BC = CD.
 \therefore the fig. ABCD is equilateral

And since BD is a diameter of the \odot ABCD,

\therefore BAD is a semicircle,

\therefore the \angle BAD is a rt. angle. III. 31

Similarly the other angles of the fig ABCD are rt. angles.

\therefore the fig ABCD is a square,
and it is inscribed in the given circle

Q. E. D.

PROPOSITION 7 PROBLEM

To circumscribe a square about a given circle

Let ABCD be the given circle.

it is required to circumscribe a square about it

Find E the centre of the \odot ABCD

III 1.

and draw two diameters AC, BD perp to one another

I 11

Through A, B, C, D draw FG, GH, HK, KF perp to EA, EB, EC, ED

Then the fig GK shall be the square required

Because FG, GH, HK, KF are drawn perp to radii at their extremities,

FG, GH, HK, KF are tangents to the circle

III 16

And because the \angle AEB, EBG are both rt angles, Constr

GH is par^l to AC

I 28

Similarly FK is par^l to AC

and in like manner GF, BD, HK are par^l.

Hence the figs GK, GC, AK, GD, BK, GE are par^{ms}

GF and HK each = BD,

also GH and FK each = AC.

but AC = BD,

GF, FK, KH, HG are all equal

that is, the fig GK is equilateral

And since the fig GE is a par^m,

the \angle BGA = the \angle BEA,

I 34

but the \angle BEA is a rt angle,

Constr

the \angle at G is a rt angle

Similarly the \angle at F, K, H are rt angles

the fig GK is a square, and it has been circumscribed about the \odot ABCD.

Q E F

PROPOSITION 8 PROBLEM

To inscribe a circle in a given square

Let ABCD be the given square
it is required to inscribe a circle in the sq ABCD

Bisect the sides AB, AD at F and E 1. 10.

Through E draw EH par^l to AB or DC. 1. 31.

and through F draw FK par^l to AD or BC, meeting EH at G.

Now AB = AD, being the sides of a square,
and their halves are equal, Constr

∴ AF = AE Ax. 7.

But the fig AG is a par^m; Constr

∴ AF = GE, and AE = GF,

GE = GF.

Similarly it may be shewn that GE = GK, and GK = GH

∴ GF, GE, GK, GH are all equal.

From centre G, with radius GE, describe a circle;
this circle must pass through the points F, E, K, H.

and it will be touched by BA, AD, DC, CB, III. 16.

for GF, GE, GK, GH are radii,

and the angles at F, E, K, H are rt angles 1. 29

Hence the \odot FEKH is inscribed in the sq. ABCD.

Q. E. D.

[For Exercises see p. 263]

PROPOSITION 9 PROBLEM

To circumscribe a circle about a given square

Let ABCD be the given square
it is required to circumscribe a circle about the sq ABCD

Join AC, BD, intersecting at E.

Then in the Δ^s BAC, DAC,

Because $\begin{cases} BA = DA, & \text{1 Def 28.} \\ \text{and AC is common,} \\ \text{and BC = DC,} & \text{1 Def 28} \end{cases}$

. the $\angle BAC = \text{the } \angle DAC$ 1 8

that is, the diagonal AC bisects the $\angle BAD$

Similarly the remaining angles of the square are bisected
by the diagonals AC or BD.

Hence each of the \angle^s EAD, EDA is half a rt angle,
the $\angle EAD = \text{the } \angle EDA$.

EA = ED 1 6

Similarly it may be shewn that ED = EC, and EC = EB
EA, EB, EC, ED are all equal

From centre E, with radius EA, describe a circle
this circle must pass through the points A, B, C, D, and is
therefore circumscribed about the sq ABCD Q E F

✓ **DEFINITION** A rectilineal figure about which a circle may be described is said to be **Cyclic**.

EXERCISES ON PROPOSITIONS 6—9.

1 If a circle can be inscribed in a quadrilateral, shew that the sum of one pair of opposite sides is equal to the sum of the other pair.

2 If the sum of one pair of opposite sides of a quadrilateral is equal to the sum of the other pair, shew that a circle may be inscribed in the figure

[Bisect two adjacent angles of the figure, and so describe a circle to touch three of its sides. Then prove indirectly by means of the last exercise that this circle must also touch the fourth side.]

3 Prove that a rhombus and a square are the only parallelograms in which a circle can be inscribed

4. All cyclic parallelograms are rectangular.

5 The greatest rectangle which can be inscribed in a given circle is a square

6 Circumscribe a rhombus about a given circle

7 All squares circumscribed about a given circle are equal

8 The area of a square circumscribed about a circle is double of the area of the inscribed square

9 ABCD is a square inscribed in a circle, and P is any point on the arc AD. shew that the side AD subtends at P an angle three times as great as that subtended at P by any one of the other sides.

10 Inscribe a square in a given square ABCD so that one of its angular points should be at a given point X in AB

11 In a given square inscribe the square of minimum area

12. Describe (i) a circle, (ii) a square about a given rectangle

13 Inscribe (i) a circle, (ii) a square in a given quadrant

14 In a given circle inscribe a rectangle equal to a given rectilinear figure

15 ABCD is a square inscribed in a circle, and P is any point on the circumference, shew that the sum of the squares on PA, PB, PC, PD is double the square on the diameter [See Ex 24, p 147]

I 6.

Constr

I 5

Proved

Q E F

$DC = DB,$
 that is, $DC = CA.$
 \therefore the $\angle CAD =$ the $\angle CDA,$
 the sum of the $\angle^s CAD, CDA =$ twice the angle at A
 But the $\angle ADB =$ the sum of the $\angle^s CAD, CDA,$
 each of the $\angle^s ABD, ADB =$ twice the angle at A

EXERCISES ON PROPOSITION 10

1 In an isosceles triangle in which each of the angles at the base is double of the vertical angle, shew that the vertical angle is one-fifth of two right angles

2 Divide a right angle into five equal parts

3 Describe an isosceles triangle whose vertical angle shall be three times either angle at the base Point out a triangle of this kind in the figure of Proposition 10

4 In the figure of Proposition 10, if the two circles intersect at F, shew that $BD = DF$

5 In the figure of Proposition 10, shew that the circle ACD is equal to the circle circumscribed about the triangle ABD

6 In the figure of Proposition 10, if the two circles intersect at F, shew that

(i) BD, DF are sides of a regular decagon inscribed in the circle EBD

(ii) AC, CD, DF are sides of a regular pentagon inscribed in the circle ACD

7 In the figure of Proposition 10, shew that the centre of the circle circumscribed about the triangle DBC is the middle point of the arc CD

8 In the figure of Proposition 10, if I is the centre of the circle inscribed in the triangle ABD, and I', S' the centres of the inscribed and circumscribed circles of the triangle DBC, shew that $S'I = S'I'$.

PROPOSITION 11 PROBLEM

To inscribe a regular pentagon in a given circle

Let ABC be a given circle

it is required to inscribe a regular pentagon in the $\odot ABC$

Describe an isosceles $\triangle FGH$, having each of the angles at G and H double of the angle at F IV 10

In the $\odot ABC$ inscribe the $\triangle ACD$ equiangular to the $\triangle FGH$, IV 2

so that each of the \angle^s ACD, ADC is double of the \angle CAD

Bisect the \angle^s ACD, ADC by CE and DB, which meet the \odot^{ce} at E and B I 9

Join AB, BC, AE, ED

Then ABCDE shall be the required regular pentagon

Because each of the \angle^s ACD, ADC = twice the \angle CAD, and because the \angle^s ACD, ADC are bisected by CE, DB,

the five \angle^s ADB, BDC, CAD, DCE, ECA are all equal

the five arcs AB, BC, CD, DE, EA are all equal III 26

the five chords AB, BC, CD, DE, EA are all equal III 29

the pentagon ABCDE is equilateral

Again the arc AB = the arc DE, Proved

to each of these equals add the arc BCD,

the whole arc ABCD = the whole arc BCDE

hence the angles at the \odot^{ce} which stand upon these equal arcs are equal, III 27

that is, the \angle AED = the \angle BAE

In like manner the remaining angles of the pentagon may be shewn to be equal,

\therefore the pentagon is equiangular

Hence the pentagon, being both equilateral and equiangular, is regular, and it is inscribed in the $\odot ABC$ Q I P

PROPOSITION 12. PROBLEM.

To circumscribe a regular pentagon about a given circle.

Let ABCD be the given circle :

it is required to circumscribe a regular pentagon about it.

Inscribe a regular pentagon in the \odot ABCD, IV. 11.

and let A, B, C, D, E be its angular points.

At the points A, B, C, D, E draw GH, HK, KL, LM, MG,
tangents to the circle III. 17.

Then shall GHKLM be the required regular pentagon

Find F the centre of the \odot ABCD ; III 1
and join FB, FK, FC, FL, FD.

Then in the two \triangle^s BFK, CFK,

Because { BF = CF, being radii of the circle,
and FK is common :
and KB = KC, being tangents to the circle from
the same point K. III 17 Cor

the \angle BFK = the \angle CFK, I. 8.

also the \angle BKF = the \angle CKF I. 8. Cor.

Hence the \angle BFC = twice the \angle CFK,

and the \angle BKC = twice the \angle CKF.

Similarly it may be shewn

that the \angle CFD = twice the \angle CFL,
and that the \angle CLD = twice the \angle CLF

But since the arc BC = the arc OD, IV. 11.

the \angle BFC = the \angle CFD ; III. 27.

and the halves of these angles are equal,

that is, the \angle CFK = the \angle CFL.

PROPOSITION 13. PROBLEM

To inscribe a circle in a given regular pentagon

Let $ABCDE$ be the given regular pentagon.
it is required to inscribe a circle within it

Bisect two consecutive \angle^s BCD , CDE by CF and DF
which intersect at F . I 9.

Join FB ,
and draw FH , FK perp to BC , CD I 12

Then in the \triangle^s BCF , DCF ,
Because $\begin{cases} BC = DC, \\ \text{and } CF \text{ is common to both,} \\ \text{and the } \angle BCF = \text{the } \angle DCF, \\ \text{the } \angle CBF = \text{the } \angle CDF. \end{cases}$ Hyp. Constr I 4

But the $\angle CDF$ is half an angle of the regular pentagon
also the $\angle CBF$ is half an angle of the regular pentagon
that is, FB bisects the $\angle ABC$

So it may be shewn that if FA , FE were joined, these
lines would bisect the \angle^s at A and E

Again, in the \triangle^s FCH , FCK ,
Because $\begin{cases} \text{the } \angle FCH = \text{the } \angle FCK, \\ \text{and the } \angle FHC = \text{the } \angle FKC \text{ being rt angles,} \\ \text{also } FC \text{ is common,} \end{cases}$ Constr I 26
 $\therefore FH = FK$

Similarly if FG , FM , FL be drawn perp. to BA , AE , ED ,
it may be shewn that the five perpendiculars drawn from F
to the sides of the pentagon are all equal

From centre F , with radius FH , describe a circle, this circle must pass through the points H, K, L, M, G , and it will be touched at these points by the sides of the pentagon, for the \angle^s at H, K, L, M, G are rt \angle^s *Constr*
the $\bigcirc HKLMG$ is inscribed in the given pentagon QEF

COROLLARY *The bisectors of the angles of a regular pentagon meet at a point*

In the same way it may be shewn that the bisectors of the angles of any regular polygon meet at a point [See Ex 1, p 274]

[For Exercises on Regular Polygons see p 276]

MISCELLANEOUS EXERCISES

1 Two tangents AB, AC are drawn from an external point A to a given circle describe a circle to touch AB, AC and the convex arc intercepted by them on the given circle

2 ABC is an isosceles triangle, and from the vertex A a straight line is drawn to meet the base at D and the circumference of the circumscribed circle at E shew that AB is a tangent to the circle circumscribed about the triangle BDE

3 An equilateral triangle is inscribed in a given circle shew that twice the square on one of its sides is equal to three times the area of the square inscribed in the same circle

4 ABC is an isosceles triangle in which each of the angles at B and C is double of the angle at A shew that the square on AB is equal to the rectangle AB, BC with the square on BC

PROPOSITION 14. PROBLEM.

To circumscribe a circle about a given regular pentagon.

Let ABCDE be the given regular pentagon :
it is required to circumscribe a circle about it

Bisect the \angle^s BCD, CDE by CF, DF intersecting at F. I. 9.
Join FB, FA, FE

Then in the Δ^s BCF, DCF,

Because $\left\{ \begin{array}{l} BC = DC, \\ \text{and CF is common to both,} \\ \text{and the } \angle BCF = \text{the } \angle DCF, \\ \text{the } \angle CBF = \text{the } \angle CDF. \end{array} \right. \quad \begin{array}{l} \text{Hyp.} \\ \text{Constr} \\ \text{I. 4.} \end{array}$

But the $\angle CDF$ is half an angle of the regular pentagon
also the $\angle CBF$ is half an angle of the regular pentagon
that is, FB bisects the $\angle ABC$.

So it may be shewn that FA, FE bisect the \angle^s at A and E

Now the \angle^s FCD, FDC are each half an angle of the
given regular pentagon,

\therefore the $\angle FCD = \text{the } \angle FDC,$ IV. Def.
 $\therefore FC = FD$ I. 6

Similarly it may be shewn that FA, FB, FC, FD, FE are
all equal

From centre F, with radius FA describe a circle :
this circle must pass through the points A, B, C, D, E,
and therefore is circumscribed about the given pentagon

Q. E. F.

In the same way a circle may be circumscribed about any regular
polygon

PROPOSITION 15 PROBLEM

To inscribe a regular hexagon in a given circle

Let $ABDF$ be the given circle
it is required to inscribe a regular hexagon in it

Find G the centre of the $\odot ABDF$, III 1
and draw a diameter AGD

From centre D , with radius DG , describe the $\odot EGCH$

Join CG , EG , and produce them to cut the \odot^{ce} of the
given circle at F and B

Join AB , BC , CD , DE , EF , FA

Then $ABCDEF$ shall be the required regular hexagon

Now $GE = GD$, being radii of the $\odot ACE$,
and $DG = DE$, being radii of the $\odot EHC$

GE , ED , DG are all equal, and the $\triangle EGD$ is equilateral

Hence the $\angle EGD =$ one-third of two rt angles I 32

Similarly the $\angle DGC =$ one-third of two rt angles

But the $\angle^s EGD$, DGC , CGB together = two rt angles, I 13

the remaining $\angle CGB =$ one-third of two rt angles

the three $\angle^s EGD$, DGC , CGB are equal to one another

And to these angles the vert opp $\angle^s BGA$, AGF , FGE
are respectively equal

the $\angle^s EGD$, DGC , CGB , BGA , AGF , FGE are all equal,

the arcs ED , DC , CB , BA , AF , FE are all equal, III 26

the chords ED , DC , CB , BA , AF , FE are all equal III 29
the hexagon is equilateral

Again the arc $FA =$ the arc DE *Proved*

to each of these equals add the arc $ABCD$,

then the whole arc $FABCD =$ the whole arc $ABCDE$

hence the angles at the \odot^{ce} which stand on these equal arcs
are equal,

that is, the $\angle FED = \text{the } \angle AFE$ III 27

In like manner the remaining angles of the hexagon may be shewn to be equal

\therefore the hexagon is equiangular

the hexagon is regular, and it is inscribed in the $\odot ABDF$
Q E F

COROLLARY *The side of a regular hexagon inscribed in a circle is equal to the radius of the circle*

PROPOSITION 16 PROBLEM

To inscribe a regular quindecagon in a given circle

Let ABCD be the given circle
it is required to inscribe a regular quindecagon in it

In the $\odot ABCD$ inscribe an equilateral triangle, IV 2
and let AC be one of its sides

In the same circle inscribe a regular pentagon, IV. 11
and let AB be one of its sides

Then of such equal parts as the whole \odot^{ce} contains fifteen,
the arc AC, which is one-third of the \odot^{ce} , contains five,
and the arc AB, which is one-fifth of the \odot^{ce} , contains three,
their difference, the arc BC, contains two

Bisect the arc BC at E. III 30

then each of the arcs BE, EC is one-fifteenth of the \odot^{ce}

if BE, EC be joined, and st lines equal to them be
placed successively round the circle, a regular quindecagon
will be inscribed in it Q E F

NOTE ON REGULAR POLYGONS

The following propositions, proved by Euclid for a regular pentagon, hold good for all regular polygons

1 *The bisectors of the angles of any regular polygon are concurrent*

Let D, E, A, B, C be consecutive angular points of a regular polygon of any number of sides

Bisect the \angle 's EAB, ABC by AO, BO, which intersect at O

Join EO

It is required to prove that EO bisects the \angle DEA

For in the Δ 's EAO, BAO,
 Because $\left\{ \begin{array}{l} EA=BA, \text{ being sides of a regular polygon,} \\ \text{and AO is common,} \\ \text{and the } \angle \text{EAO}=\text{the } \angle \text{BAO,} \\ \text{the } \angle \text{OEA}=\text{the } \angle \text{OBA} \end{array} \right.$ Constr
1 4.

But the \angle OBA is half the \angle ABC, Constr.
 also the \angle ABC = the \angle DEA, since the polygon is regular,
 the \angle OEA is half the \angle DEA.
 that is, EO bisects the \angle DEA

Similarly if O be joined to the remaining angular points of the polygon, it may be proved that each joining line bisects the angle to whose vertex it is drawn

That is to say, the bisectors of the angles of the polygon meet at the point O Q E D

COROLLARIES Since the \angle EAB = the \angle ABC, Hyp
 and since the \angle 's OAB, OBA are respectively half of the \angle 's EAB, ABC,
 the \angle OAB = the \angle OBA

\therefore OA = OB 1 6
 Similarly OE = OA

Hence *The bisectors of the angles of a regular polygon are all equal and a circle described from the centre O, with radius OA, will be circumscribed about the polygon*

Also it may be shewn, as in Proposition 13, that perpendiculars drawn from O to the sides of the polygon are all equal, therefore a circle described from centre O with any one of these perpendiculars as radius will be inscribed in the polygon

2 If a polygon inscribed in a circle is equilateral, it is also equiangular

Let AB, BC, CD be consecutive sides of an equilateral polygon inscribed in the $\odot ADK$, then shall this polygon be equiangular

Because the chord $AB =$ the chord DC , *Hyp*
 \therefore the minor arc $AB =$ the minor arc DC III. 28

To each of these equals add the arc AKD :
 then the arc $BAKD =$ the arc $AKDC$,
 \therefore the angles at the O^e , which stand on these equal arcs, are equal,

that is, the $\angle BCD =$ the $\angle ABC$ III. 27

Similarly the remaining angles of the polygon may be shewn to be equal.

\therefore the polygon is equiangular

Q E D

3 If a polygon inscribed in a circle is equiangular, it is also equilateral, provided that the number of its sides is odd

[Observe that Theorems 2 and 3 are only true of polygons inscribed in a circle.]

The accompanying figures are sufficient to shew that otherwise a polygon may be equilateral without being equiangular, Fig 1, or equiangular without being equilateral, Fig 2]

NOTE The following extensions of Euclid's constructions for Regular Polygons should be noticed

By continual bisection of arcs, we are enabled to divide the circumference of a circle,

by means of Proposition 6, into 4, 8, 16, . . . $2 \cdot 2^n$, equal parts,
 by means of Proposition 15, into 3, 6, 12, . . . $3 \cdot 2^n$, equal parts,
 by means of Proposition 11, into 5, 10, 20, . . . $5 \cdot 2^n$, equal parts,
 by means of Proposition 16, into 15, 30, 60, . . . $15 \cdot 2^n$, equal parts.

Hence we can inscribe in a circle a regular polygon the number of whose sides is included in any one of the formulæ $2 \cdot 2^n$, $3 \cdot 2^n$, $5 \cdot 2^n$, $15 \cdot 2^n$, n being any positive integer. In addition to these, it has been shewn that a regular polygon of $2^n + 1$ sides, provided $2^n + 1$ is a prime number, may be inscribed in a circle.

EXERCISES ON PROPOSITIONS 11—16

1 Express in terms of a right angle the magnitude of an angle of the following *regular* polygons

- (i) a pentagon, (ii) a hexagon, (iii) an octagon,
(iv) a decaagon, (v) a quindecagon

2 The angle of a regular pentagon is trisected by the straight lines which join it to the opposite vertices

3 In a polygon of n sides the straight lines which join any angular point to the vertices not adjacent to it, divide the angle into $n - 2$ equal parts

4 Shew how to construct on a given straight line

- (i) a regular pentagon, (ii) a regular hexagon, (iii) a regular octagon

5 An equilateral triangle and a regular hexagon are inscribed in a given circle, shew that

- (i) the area of the triangle is half that of the hexagon,
(ii) the square on the side of the triangle is three times the square on the side of the hexagon

6 ABCDE is a regular pentagon, and AC, BE intersect at H shew that

- (i) $AB = CH = EH$
(ii) AB is a tangent to the circle circumscribed about the triangle BHC
(iii) AC and BE cut one another in medial section

7 The straight lines which join alternate vertices of a regular pentagon intersect so as to form another regular pentagon

8 The straight lines which join alternate vertices of a regular polygon of n sides, intersect so as to form another regular polygon of n sides

If $n = 6$, shew that the area of the resulting hexagon is one third of the given hexagon

9 By means of iv 16, inscribe in a circle a triangle whose angles are as the numbers 2, 5, 8

10 Shew that the area of a regular hexagon inscribed in a circle is three-fourths of that of the corresponding circumscribed hexagon

THEOREMS AND EXAMPLES ON BOOK IV.

I ON THE TRIANGLE AND ITS CIRCLES

1 D, F, E are the points of contact of the inscribed circle of the triangle ABC, and D_1, F_1, E_1 the points of contact of the escribed circle, which touches BC and the other sides produced a, b, c denote the lengths of the sides BC, CA, AB, s the semi-perimeter of the triangle, and r, r_1 the radii of the inscribed and escribed circles

Prove the following equalities —

- (i) $AE = AF = s - a,$
 $BD = BE = s - b,$
 $CD = CF = s - c$
- (ii) $AE_1 = AF_1 = s$
- (iii) $CD_1 = CF_1 = s - b,$
 $BD_1 = BE_1 = s - c$
- (iv) $CD = BD_1$ and $BD = CD_1$
- (v) $EE_1 = FF_1 = a$
- (vi) The area of the $\triangle ABC$
 $= rs = r_1(s - a)$

2 In the triangle ABC , I is the centre of the inscribed circle, and I_1, I_2, I_3 the centres of the escribed circles touching respectively the sides BC, CA, AB and the other sides produced

Prove the following properties —

- (i) The points A, I, I_1 are collinear, so are B, I, I_2 , and C, I, I_3
- (ii) The points I_2, A, I_3 are collinear; so are I_3, B, I_1 , and I_1, C, I_2
- (iii) The triangles BI_1C, CI_2A, AI_3B are equiangular to one another
- (iv) The triangle $I_1I_2I_3$ is equiangular to the triangle formed by joining the points of contact of the inscribed circle
- (v) Of the four points I, I_1, I_2, I_3 each is the orthocentre of the triangle whose vertices are the other three
- (vi) The four circles, each of which passes through three of the points I, I_1, I_2, I_3 , are all equal.

3 With the notation of page 277, shew that in a triangle ABC, if the angle at C is a right angle,

$$r = s - c, \quad r_1 = s - b, \quad r_2 = s - a, \quad r_3 = ?$$

4 With the figure given on page 278, shew that if the circles whose centres are I, I_1, I_2, I_3 touch BC at D, D_1, D_2, D_3 , then

$$\begin{array}{ll} \text{(i)} & DD_2 = D_1D_3 = b \\ \text{(ii)} & DD_3 = D_1D_2 = c \\ \text{(iii)} & D_2D_3 = b + c \\ \text{(iv)} & DD_1 = b - c \end{array}$$

5 Shew that the orthocentre and vertices of a triangle are the centres of the inscribed and escribed circles of the pedal triangle

[See Ex 20, p 225]

6 Given the base and vertical angle of a triangle, find the locus of the centre of the inscribed circle

[See Ex 36, p 228]

7. Given the base and vertical angle of a triangle, find the locus of the centre of the escribed circle which touches the base.

8 Given the base and vertical angle of a triangle, shew that the centre of the circumscribed circle is fixed

9 Given the base BC, and the vertical angle A of a triangle, find the locus of the centre of the escribed circle which touches AC.

10 Given the base, the vertical angle, and the radius of the inscribed circle, construct the triangle

11 Given the base, the vertical angle, and the radius of the escribed circle, (i) which touches the base, (ii) which touches one of the sides containing the given angle, construct the triangle

12 Given the base, the vertical angle, and the point of contact with the base of the inscribed circle, construct the triangle

13. Given the base, the vertical angle, and the point of contact with the base, or base produced, of an escribed circle, construct the triangle

14 From an external point A two tangents AB, AC are drawn to a given circle, and the angle BAC is bisected by a straight line which meets the circumference in I and I_1 . shew that I is the centre of the circle inscribed in the triangle ABC, and I_1 the centre of one of the escribed circles

15 I is the centre of the circle inscribed in a triangle, and I_1, I_2, I_3 the centres of the escribed circles, shew that II_1, II_2, II_3 are bisected by the circumference of the circumscribed circle

16 ABC is a triangle, and I_2, I_3 the centres of the escribed circles which touch AC, and AB respectively. shew that the points B, C, I_2, I_3 lie upon a circle whose centre is on the circumference of the circle circumscribed about ABC.

17 With three given points as centres describe three circles touching one another two by two. How many solutions will there be?

18 Two tangents AB, AC are drawn to a given circle from an external point A , and in AB, AC two points D and E are taken so that DE is equal to the sum of DB and EC . shew that DE touches the circle.

19 Given the perimeter of a triangle, and one angle in magnitude and position shew that the opposite side always touches a fixed circle.

20 Given the centres of the three escribed circles, construct the triangle.

21 Given the centre of the inscribed circle, and the centres of two escribed circles, construct the triangle.

22 Given the vertical angle, perimeter, and the length of the bisector of the vertical angle, construct the triangle.

23 Given the vertical angle, perimeter, and altitude, construct the triangle.

24 Given the vertical angle, perimeter, and radius of the inscribed circle, construct the triangle.

25 Given the vertical angle, the radius of the inscribed circle, and the length of the perpendicular from the vertex to the base, construct the triangle.

26 Given the base, the difference of the sides containing the vertical angle, and the radius of the inscribed circle, construct the triangle. [See Ex 10, p 258]

27 Given the base and vertical angle of a triangle, find the locus of the centre of the circle which passes through the three escribed centres.

28 In a triangle ABC , I is the centre of the inscribed circle, shew that the centres of the circles circumscribed about the triangles BIC, CIA, AIB lie on the circumference of the circle circumscribed about the given triangle.

29 In a triangle ABC , the inscribed circle touches the base BC at D , and r, r_1 are the radii of the inscribed circle and of the escribed circle which touches BC . shew that $r \cdot r_1 = BD \cdot DC$.

30 ABC is a triangle, D, E, F the points of contact of its inscribed circle, and $D'E'F'$ is the pedal triangle of the triangle DEF . shew that the sides of the triangle $D'E'F'$ are parallel to those of ABC .

31 In a triangle ABC the inscribed circle touches BC at D . Shew that the circles inscribed in the triangles ABD, ACD touch one another.

ON THE NINE-POINTS CIRCLE

32 In any triangle the middle points of the sides, the feet of the perpendiculars drawn from the vertices to the opposite sides, and the middle points of the lines joining the orthocentre to the vertices are concyclic

In the $\triangle ABC$, let X, Y, Z be the middle points of the sides BC, CA, AB , let D, E, F be the feet of the perpⁿ drawn to these sides from A, B, C ; let O be the orthocentre, and α, β, γ the middle points of OA, OB, OC .

then shall the nine points $X, Y, Z, D, E, F, \alpha, \beta, \gamma$ be concyclic

Join $XY, XZ, X\alpha, Y\alpha, Z\alpha$
Now from the $\triangle ABO$, since $AZ = ZB$,
and $A\alpha = \alpha O$,

$Z\alpha$ is par^l to BO Ex 2, p 96

And from the $\triangle ABC$, since $BZ = ZA$,
and $BX = XC$,

ZX is par^l to AC

But BO makes a rt angle with AC ,
the $\angle XZ\alpha$ is a rt angle

Similarly, the $\angle XY\alpha$ is a rt angle

∴ the points X, Z, α, Y are concyclic.

that is, α lies on the C^c of the circle, which passes through X, Y, Z ,
and $X\alpha$ is a diameter of this circle

Similarly it may be shewn that β and γ lie on the C^c of the circle which passes through X, Y, Z

Again, since αDX is a rt angle,
the circle on $X\alpha$ as diameter passes through D .

Similarly it may be shewn that E and F lie on the circumference of the same circle

the points $X, Y, Z, D, E, F, \alpha, \beta, \gamma$ are concyclic $Q.E.D.$

From this property the circle which passes through the middle points of the sides of a triangle is called the **Nine Points Circle**, many of its properties may be derived from the fact of its being the circle circumscribed about the pedal triangle

33 To prove that

- (i) the centre of the nine-points circle is the middle point of the straight line which joins the orthocentre to the circumscribed centre
 (ii) the radius of the nine points circle is half the radius of the circumscribed circle
 (iii) the centroid is collinear with the circumscribed centre, the nine-points centre, and the orthocentre

In the $\triangle ABC$, let X, Y, Z be the middle points of the sides, D, E, F the feet of the perp^s, O the orthocentre, S and N the centres of the circumscribed and nine-points circles respectively

(i) To prove that N is the middle point of SO

It may be shewn that the perp to XD from its middle point bisects SO ,
 Ex 14, p 98

Similarly the perp to EY at its middle point bisects SO

that is, these perp^s intersect at the middle point of SO

And since XD and EY are chords of the nine-points circle, the intersection of the lines which bisect XD and EY at rt angles is its centre

the centre N is the middle point of SO

(ii) To prove that the radius of the nine points circle is half the radius of the circumscribed circle

By the last Proposition, $X\alpha$ is a diameter of the nine-points circle
 the middle point of $X\alpha$ is its centre

but the middle point of SO is also the centre of the nine-points circle
 (Proved)

Hence $X\alpha$ and SO bisect one another at N

Then from the $\triangle SNX$, $ON\alpha$

Because $\left\{ \begin{array}{l} SN=ON, \\ \text{and } NX=N\alpha, \\ \text{and the } \angle SNX = \text{the } \angle ON\alpha, \\ SX=O\alpha \\ =A\alpha \end{array} \right.$

I 15

I 4

And SX is also par^l to $A\alpha$,

$SA=X\alpha$

I 33

But SA is a radius of the circumscribed circle,
 and $X\alpha$ is a diameter of the nine points circle,
 the radius of the nine points circle is half the radius of the circumscribed circle

(iii) To prove that the centroid is collinear with points S, N, O.

Join AX and draw ag par^l to SO

Let AX meet SO at G

Then from the $\triangle AGO$, since $Aa = aO$ and ag is par^l to OG,
 $\therefore Ag = gG$ Ex. 13, p 98.

And from the $\triangle Xag$, since $aN = NX$, and NG is par^l to ag ,
 $gG = GX$ Ex. 13, p 98

$\therefore AG = \frac{2}{3}$ of AX,

$\therefore G$ is the centroid of the triangle ABC

That is, the centroid is collinear with the points S, N, O Q.F.D

34. Given the base and vertical angle of a triangle, find the locus of the centre of the nine-points circle.

35 The nine-points circle of any triangle ABC, whose centre is O, is also the nine-points circle of each of the triangles AOB, BOC, COA

36 If l, l_1, l_2, l_3 are the centres of the inscribed and escribed circles of a triangle ABC, then the circle circumscribed about ABC is the nine-points circle of each of the four triangles formed by joining three of the points l, l_1, l_2, l_3

37. All triangles which have the same orthocentre and the same circumscribed circle, have also the same nine-points circle.

38 If S, l are the centres, and R, r the radii of the circumscribed and inscribed circles of a triangle, and if N is the centre of the nine-points circle, prove that

$$(i) \quad Sl^2 = R^2 - 2Rr,$$

$$(ii) \quad Nl = \frac{1}{2}R - r.$$

And establish corresponding properties for the escribed circles.

39 Employ the preceding theorem to shew that the nine-points circle touches the inscribed and escribed circles of a triangle.

II MISCELLANEOUS EXAMPLES

1 If four circles are described to touch every three sides of a quadrilateral, shew that their centres are concyclic.

2. If the straight lines which bisect the angles of a rectilinear figure are concurrent, a circle may be inscribed in the figure.

3 Within a given circle describe three equal circles touching one another and the given circle

4 The perpendiculars drawn from the centres of the three escribed circles of a triangle to the sides which they touch, are concurrent

5 Given an angle and the radii of the inscribed and circumscribed circles, construct the triangle

6. Given the base, an angle at the base, and the distance between the centre of the inscribed circle and the centre of the escribed circle which touches the base, construct the triangle

7 In a given circle inscribe a triangle such that two of its sides may pass through two given points, and the third side be of given length

8 In any triangle ABC , I , I_1 , I_2 , I_3 are the centres of the inscribed and escribed circles, and S_1 , S_2 , S_3 are the centres of the circles circumscribed about the triangles BIC , CIA , AIB shew that the triangle $S_1S_2S_3$ has its sides parallel to those of the triangle $I_1I_2I_3$, and is one fourth of it in area also that the triangles ABC and $S_1S_2S_3$ have the same circumscribed circle

9 O is the orthocentre of a triangle ABC shew that

$$AO^2 + BC^2 = BO^2 + CA^2 = CO^2 + AB^2 = d^2,$$

where d is the diameter of the circumscribed circle

10 If from any point within a regular polygon of n sides perpendiculars are drawn to the sides the sum of the perpendiculars is equal to n times the radius of the inscribed circle

11 The sum of the perpendiculars drawn from the vertices of a regular polygon of n sides on any straight line is equal to n times the perpendicular drawn from the centre of the inscribed circle

12 The area of a cyclic quadrilateral is independent of the order in which the sides are placed in the circle

13 Of all quadrilaterals which can be formed of four straight lines of given length, that which is cyclic has the maximum area

14 Of all polygons of a given number of sides, which may be inscribed in a given circle, that which is regular has the maximum area and the maximum perimeter

15 Of all polygons of a given number of sides circumscribed about a given circle, that which is regular has the minimum area and the minimum perimeter

16 Given the vertical angle of a triangle in position and magnitude, and the sum of the sides containing it find the locus of the centre of the circumscribed circle

17 P is any point on the circumference of a circle circumscribed about an equilateral triangle ABC shew that $PA^2 + PB^2 + PC^2$ is constant

BOOK V.

Book V. treats of Ratio and Proportion

INTRODUCTORY

The first four books of Euclid deal with the absolute equality or inequality of Geometrical magnitudes. In the Fifth Book magnitudes are compared by considering their *ratio*, or relative greatness.

The meaning of the words *ratio* and *proportion* in their simplest arithmetical sense, as contained in the following definitions, is probably familiar to the student.

The ratio of one number to another is the multiple, part, or parts that the first number is of the second, and it may therefore be measured by the fraction of which the first number is the numerator and the second the denominator.

Four numbers are in proportion when the ratio of the first to the second is equal to that of the third to the fourth.

But it will be seen that these definitions are inapplicable to Geometrical magnitudes for the following reasons.

(1) Pure Geometry deals only with *concrete magnitudes*, represented by diagrams, but not referred to any common unit in terms of which they are measured. In other words, it makes no use of *number* for the purpose of comparison between different magnitudes.

(2) It commonly happens that Geometrical magnitudes of the same kind are *incommensurable*, that is, they are such that it is impossible to express them *exactly* in terms of some common unit.

For example, we can make comparison between the side and diagonal of a square, and we may form an idea of their relative greatness, but it can be shewn that it is impossible to divide either of them into equal parts of which the other contains an exact number. And as the magnitudes we meet with in Geometry are more often incommensurable than not, it is clear that it would not always be possible to exactly represent such magnitudes by *numbers*, even if reference to a common unit were not foreign to the principles of Euclid.

It is therefore necessary to establish the Geometrical Theory of Proportion on a basis quite independent of Arithmetical principles. This is the aim of Euclid's Fifth Book.

We shall employ the following notation

Capital letters, A, B, C, will be used to denote the magnitudes themselves, *not any numerical or algebraical measures of them*, and small letters, m, n, p , will be used to denote whole numbers. Also it will be assumed that multiplication, in the sense of repeated addition, can be applied to any magnitude, so that m A or mA will denote the magnitude A taken m times.

The symbol $>$ will be used for the words *greater than*, and $<$ for *less than*.

DEFINITIONS

1 A greater magnitude is said to be a multiple of a less, when the greater contains the less an *exact* number of times

2 A less magnitude is said to be a submultiple of a greater, when the less is contained an *exact* number of times in the greater

The following properties of multiples will be assumed as self evident

(1) $mA > =$ or $< mB$ according as $A > =$ or $< B$, and conversely

(2) $mA + mB + = m(A + B +)$

(3) If $A > B$, then $mA - mB = m(A - B)$

(4) $mA + nA + = (m + n +)A$

(5) If $m > n$, then $mA - nA = (m - n)A$

(6) $m \ nA = nm \ A = nm \ A = n \ mA$

3 The Ratio of one magnitude to another of the same kind is the relation which the first bears to the second in respect of quantuplicity

The ratio of A to B is denoted thus, $A : B$, and A is called the antecedent, B the consequent of the ratio

The term *quantuplicity* denotes the capacity of the first magnitude to contain the second with or without remainder. If the magnitudes are commensurable, their quantuplicity may be expressed *numerically* by observing what multiples of the two magnitudes are equal to one another

Thus if $A = ma$, and $B = na$, it follows that $nA = mB$. In this case $A = \frac{m}{n} B$, and the quantuplicity of A with respect to B is the arithmetical fraction $\frac{m}{n}$

But if the magnitudes are incommensurable, no multiple of the first can be equal to any multiple of the second, and therefore the quantuplicity of one with respect to the other cannot exactly be expressed numerically in this case it is determined by examining how the multiples of one magnitude are distributed among the multiples of the other

Thus, let all the multiples of A be formed, the scale extending *ad infinitum*, also let all the multiples of B be formed and placed in their proper order of magnitude among the multiples of A. Thus forms the relative scale of the two magnitudes, and the quantuplicity of A with respect to B is estimated by examining how the multiples of A are distributed among those of B in their relative scale

In other words, the ratio of A to B is known, if for all integral values of m we know the multiples nB and $(n+1)B$ between which mA lies

In the case of two given magnitudes A and B, the relative scale of multiples is definite, and is different from that of A to C, if C differs from B by any magnitude however small

For let D be the difference between B and C; then however small D may be, it will be possible to find a number m such that $mD > A$. In this case, mB and mC would differ by a magnitude greater than A, and therefore could not lie between the same two multiples of A, so that after a certain point the relative scale of A and B would differ from that of A and C

[It is worthy of notice that we can always estimate the arithmetical ratio of two incommensurable magnitudes *within any required degree of accuracy*

For suppose that A and B are incommensurable, divide B into m equal parts each equal to β , so that $B = m\beta$, where m is an integer. Also suppose β is contained in A more than n times and less than $(n+1)$ times, then

$$\frac{A}{B} > \frac{n\beta}{m\beta} \text{ and } < \frac{(n+1)\beta}{m\beta},$$

$$\text{that is, } \frac{A}{B} \text{ lies between } \frac{n}{m} \text{ and } \frac{n+1}{m},$$

so that $\frac{A}{B}$ differs from $\frac{n}{m}$ by a quantity less than $\frac{1}{m}$. And since we can choose β (our unit of measurement) as small as we please, m can be made as great as we please. Hence $\frac{1}{m}$ can be made as small as we please, and two integers n and m can be found whose ratio will express that of a and b to any required degree of accuracy.]

4 The ratio of one magnitude to another is equal to that of a third magnitude to a fourth, when if any equimultiples whatever of the antecedents of the ratios are taken, and also any equimultiples whatever of the consequents, the multiple of one antecedent is greater than, equal to, or less than that of its consequent, according as the multiple of the other antecedent is greater than, equal to, or less than that of its consequent

Thus the ratio A to B is equal to that of C to D when $mC > = < nD$ according as $mA > =$ or $< nB$, whatever whole numbers m and n may be

Again, let m be any whole number whatever, and n another whole number determined in such a way that either mA is equal to nB , or mA lies between nB and $(n+1)B$, then the definition asserts that the ratio of A to B is equal to that of C to D if $mC = nD$ when $mA = nB$, or if mC lies between nD and $(n+1)D$ when mA lies between nB and $(n+1)B$

In other words, the ratio of A to B is equal to that of C to D when the multiples of A are distributed among those of B in the same manner as the multiples of C are distributed among those of D

5 When the ratio of A to B is equal to that of C to D the four magnitudes are called **proportionals**. This is expressed by saying " A is to B as C is to D ", and the proportion is written

$$A \quad B \quad C \quad D,$$

or

$$A \quad B = C \quad D$$

A and D are called the **extremes**, B and C the **means**, also D is said to be a **fourth proportional** to A , B , and C

Two terms in a proportion are said to be **homologous** when they are both antecedents, or both consequents of the ratios

[It will be useful here to compare the algebraical and geometrical definitions of proportion, and to show that each may be deduced from the other

According to the geometrical definition A , B , C , D are in proportion, when $mC > = < nD$ according as $mA > = < nB$, m and n being any positive integers whatever

According to the algebraical definition A , B , C , D are in proportion when $\frac{A}{B} = \frac{C}{D}$

(1) To deduce the geometrical definition of proportion from the algebraical definition

Since $\frac{A}{B} = \frac{C}{D}$, by multiplying both sides by $\frac{n}{n}$, we obtain

$$\frac{nA}{nB} = \frac{nC}{nD},$$

hence from the nature of fractions,

$$nC > < nD \text{ according as } nA > = < nB,$$

which is the geometrical test of proportion

(11) To deduce the algebraical definition of proportion from the geometrical definition

Given that $nC > < nD$ according as $nA > = < nB$, to prove

$$\frac{A}{B} = \frac{C}{D}.$$

If $\frac{A}{B}$ is not equal to $\frac{C}{D}$, one of them must be the greater

Suppose $\frac{A}{B} > \frac{C}{D}$, then it will be possible to find some fraction $\frac{n}{m}$ which lies between them, n and m being positive integers

$$\text{Hence} \quad \frac{A}{B} > \frac{n}{m} \quad (1),$$

$$\text{and} \quad \frac{C}{D} < \frac{n}{m} \quad (2)$$

From (1), $nA > mB$,
from (2), $mC < nD$,
and these contradict the hypothesis

Therefore $\frac{A}{B}$ and $\frac{C}{D}$ are not unequal, that is, $\frac{A}{B} = \frac{C}{D}$; which proves the proposition]

6 The ratio of one magnitude to another is greater than that of a third magnitude to a fourth, when it is possible to find equimultiples of the antecedents and equimultiples of the consequents such that while the multiple of the antecedent of the first ratio is greater than, or equal to, that of its consequent, the multiple of the antecedent of the second is not greater, or is less, than that of its consequent

This definition asserts that if whole numbers m and n can be found such that while mA is greater than nB , mC is not greater than nD , or while $mA=nB$, mC is less than nD , then the ratio of A to B is greater than that of C to D .

7 If A is equal to B , the ratio of A to B is called a ratio of equality.

If A is greater than B , the ratio of A to B is called a ratio of greater inequality.

If A is less than B , the ratio of A to B is called a ratio of less inequality.

8 Two ratios are said to be reciprocal when the antecedent and consequent of one are the consequent and antecedent of the other respectively, thus $B : A$ is the reciprocal of $A : B$.

9 Three magnitudes of the same kind are said to be proportionals, when the ratio of the first to the second is equal to that of the second to the third.

Thus A, B, C are proportionals if

$$A : B = B : C$$

B is called a mean proportional to A and C , and C is called a third proportional to A and B .

10 Three or more magnitudes are said to be in continued proportion when the ratio of the first to the second is equal to that of the second to the third, and the ratio of the second to the third is equal to that of the third to the fourth, and so on.

11 When there are any number of magnitudes of the same kind, the first is said to have to the last the ratio compounded of the ratios of the first to the second, of the second to the third, and so on up to the ratio of the last but one to the last magnitude.

For example, if A, B, C, D, E be magnitudes of the same kind, $A : E$ is the ratio compounded of the ratios $A : B$, $B : C$, $C : D$, and $D : E$.

This is sometimes expressed by the following notation

$$A : B :: C : D$$

12 If there are any number of ratios, and a set of magnitudes is taken such that the ratio of the first to the second is equal to the first ratio, and the ratio of the second to the third is equal to the second ratio, and so on, then the first of the set of magnitudes is said to have to the last the ratio compounded of the given ratios

Thus, if $A : B, C : D, E : F$ be given ratios, and if P, Q, R, S be magnitudes taken so that

$$\begin{array}{lll} P : Q & A : B, \\ Q : R & C : D, \\ R : S & E : F, \end{array}$$

then
$$P : S = \left\{ \begin{array}{l} A : B \\ C : D \\ E : F \end{array} \right.$$

13 When three magnitudes are proportionals, the first is said to have to the third the duplicate ratio of that which it has to the second

Thus if $A : B :: B : C,$

then A is said to have to C the duplicate ratio of that which it has to B

Since
$$A : C = \left\{ \begin{array}{l} A : B \\ B : C \end{array} \right.$$

it is clear that the ratio compounded of two equal ratios is the duplicate ratio of either of them

14 When four magnitudes are in *continued proportion*, the first is said to have to the fourth the triplicate ratio of that which it has to the second.

It may be shewn as above that the ratio compounded of three equal ratios is the triplicate ratio of any one of them

Although an algebraical treatment of ratio and proportion when applied to geometrical magnitudes cannot be considered exact, it will perhaps be useful here to summarise in algebraical form the principal theorems of proportion contained in Book V. The student will then perceive that its leading propositions do not introduce new ideas, but merely supply rigorous proofs, based on the geometrical definition of proportion, of results already familiar in the study of Algebra.

We shall only here give those propositions which are afterwards referred to in Book VI. It will be seen that in their algebraical form many of them are so simple that they hardly require proof.

SUMMARY OF PRINCIPAL THEOREMS OF BOOK V

PROPOSITION 1

Ratios which are equal to the same ratio are equal to one another

That is, if $A : B = X : Y$ and $C : D = X : Y$,
then $A : B = C : D$

PROPOSITION 3

If four magnitudes are proportionals, they are also proportionals when taken inversely

That is, if $A : B = C : D$,
then $B : A = D : C$

This inference is referred to as *invertendo* or *inversely*

PROPOSITION 4

(i) *Equal magnitudes have the same ratio to the same magnitude.*

For if $A = B$,
then $A : C = B : C$

(ii) *The same magnitude has the same ratio to equal magnitudes*

For if $A = B$,
then $C : A = C : B$

PROPOSITION 6.

(i) *Magnitudes which have the same ratio to the same magnitude are equal to one another*

That is, if $A : C = B : C,$

then $A = B$

(ii) *Those magnitudes to which the same magnitude has the same ratio are equal to one another*

That is, if $C : A = C : B,$

then $A = B.$

PROPOSITION 8

Magnitudes have the same ratio to one another which their equimultiples have

That is, $A : B = mA : mB,$

where m is any whole number

PROPOSITION 11

If four magnitudes of the same kind are proportionals, they are also proportionals when taken alternately

If $A : B = C : D,$

then shall $A : C = B : D$

For since $\frac{A}{B} = \frac{C}{D},$

multiplying by $\frac{B}{C},$ we have $\frac{A}{B} \cdot \frac{B}{C} = \frac{C}{D} \cdot \frac{B}{C},$

that is, $\frac{A}{C} = \frac{B}{D},$

or $A : C = B : D.$

This inference is referred to as *alternando* or *alternately*

PROPOSITION 12

If any number of magnitudes of the same kind are proportionals, then as one of the antecedents is to its consequent, so is the sum of the antecedents to the sum of the consequents

Let $A : B = C : D = E : F =$,
then shall $A + B : A + C + E + \dots = B + D + F + \dots$

For put each of the equal ratios $\frac{A}{B}, \frac{C}{D}, \frac{E}{F}$, equal to λ ,

then $A = B\lambda, C = D\lambda, E = F\lambda,$

$$\frac{A + C + E + \dots}{B + D + F + \dots} = \frac{B\lambda + D\lambda + F\lambda + \dots}{B + D + F + \dots} = \lambda = \frac{A}{B} = \frac{C}{D} = \frac{E}{F} = \dots,$$

$$A + B : A + C + E + \dots = B + D + F + \dots$$

This inference is sometimes referred to as *addendo*

PROPOSITION 13

(i) *If four magnitudes are proportionals, the sum of the first and second is to the second as the sum of the third and fourth is to the fourth*

Let $A : B = C : D$,
then shall $A + B : B = C + D : D$

For since $\frac{A}{B} = \frac{C}{D}$,

$$\frac{A}{B} + 1 = \frac{C}{D} + 1,$$

that is, $\frac{A + B}{B} = \frac{C + D}{D}$,

or $A + B : B = C + D : D$

This inference is referred to as *componendo*

(ii) *If four magnitudes are proportionals, the difference of the first and second is to the second as the difference of the third and fourth is to the fourth*

That is, if $A : B = C : D$,
then $A - B : B = C - D : D$

The proof is similar to that of the former case

This inference is referred to as *dividendo*

PROPOSITION 14

If there are two sets of magnitudes, such that the first is to the second of the first set as the first to the second of the other set, and the second to the third of the first set as the second to the third of the other, and so on to the last magnitude then the first is to the last of the first set as the first to the last of the other

First let there be three magnitudes, A, B, C, of one set, and three, P, Q, R, of another set,

and let $A : B = P : Q$,

and $B : C = Q : R$,

then shall $A : C = P : R$

For since $\frac{A}{B} = \frac{P}{Q}$, and $\frac{B}{C} = \frac{Q}{R}$,

$$\frac{A}{B} \cdot \frac{B}{C} = \frac{P}{Q} \cdot \frac{Q}{R},$$

that is, $\frac{A}{C} = \frac{P}{R}$,

or $A : C = P : R$

Similarly if $A : B = P : Q$,
 $B : C = Q : R$,
 $\quad \quad \quad = \quad \quad \quad$,
 $L : M = Y : Z$,

it can be proved that $A : M = P : Z$

This inference is referred to as *ex æquali*

COROLLARY If $A : B = P : Q$,

and $B : C = R : P$,

then shall $A : C = R : Q$

For since $\frac{A}{B} = \frac{P}{Q}$, and $\frac{B}{C} = \frac{R}{P}$;

$$\frac{A}{B} \cdot \frac{B}{C} = \frac{P}{Q} \cdot \frac{R}{P},$$

$$\frac{A}{C} = \frac{R}{Q},$$

or $A : C = R : Q$

PROPOSITION 15

If
and
then shall

$$\begin{aligned} A & B = C & D, \\ E & B = F & D, \\ A + E & B = C + F & D \end{aligned}$$

For since

$$\frac{A}{B} = \frac{C}{D}, \text{ and } \frac{E}{B} = \frac{F}{D},$$

$$\frac{A + E}{B} = \frac{C + F}{D},$$

that is,

$$A + E : B = C + F : D$$

PROPOSITION 16

If two ratios are equal, their duplicate ratios are equal, and conversely

Let

$$A : B = C : D,$$

then shall the duplicate ratio of $A : B$ be equal to the duplicate ratio of $C : D$

Let X be a third proportional to A, B ,
so that

$$A : B = B : X,$$

$$\frac{B}{X} = \frac{A}{B},$$

$$\frac{B}{X} : \frac{A}{B} = \frac{A}{B} : \frac{A}{B},$$

that is,

$$\frac{B}{X} = \frac{A^2}{B^2}$$

But $A : X$ is the duplicate ratio of $A : B$,
the duplicate ratio of $A : B = A^2 : B^2$

But since

$$A : B = C : D,$$

$$\frac{A}{B} = \frac{C}{D},$$

$$\frac{A^2}{B^2} = \frac{C^2}{D^2},$$

or

$$A^2 : B^2 = C^2 : D^2,$$

that is, the duplicate ratio of $A : B$ = the duplicate ratio of $C : D$

Conversely, let the duplicate ratio of $A : B$ be equal to the duplicate ratio of $C : D$,

then shall

$$A : B = C : D,$$

for since

$$A^2 : B^2 = C^2 : D^2,$$

$$A : B = C : D$$

PROOFS OF THE PROPOSITIONS OF BOOK V. DERIVED FROM
THE GEOMETRICAL DEFINITION OF PROPORTION

Obs The Propositions of Book V are all theorems

PROPOSITION 1

Ratios which are equal to the same ratio are equal to one another.

Let $A : B :: P : Q$, and also $C : D :: P : Q$, then shall $A : B :: C : D$.

For it is evident that two scales or arrangements of multiples which agree in every respect with a third scale, will agree with one another.

PROPOSITION 2

If two ratios are equal, the antecedent of the second is greater than, equal to, or less than its consequent according as the antecedent of the first is greater than, equal to, or less than its consequent

Let $A : B :: C : D$,
then $C > =$ or $< D$,
according as $A > =$ or $< B$

This follows at once from Def 4, by taking m and n each equal to unity.

PROPOSITION 3

If two ratios are equal, then reciprocal ratios are equal

Let $A \ B \ C \ D$,
then shall $B \ A \ D \ C$

For, by hypothesis, the multiples of A are distributed among those of B in the same manner as the multiples of C are among those of D ,
therefore also, the multiples of B are distributed among those of A in the same manner as the multiples of D are among those of C

That is, $B \ A \ D \ C$

NOTE This proposition is sometimes enunciated thus

If four magnitudes are proportionals, they are also proportionals when taken inversely,
and the inference is referred to as *invertendo* or *inversely*.

PROPOSITION 4

Equal magnitudes have the same ratio to the same magnitude, and the same magnitude has the same ratio to equal magnitudes

Let A, B, C be three magnitudes of the same kind, and let A be equal to B ,

then shall $A \ C \ B \ C$
and $C \ A \ C \ B$

Since $A = B$, then multiples are identical and therefore are distributed in the same way among the multiples of C

$A \ C \ B \ C$, Def 4
also, *invertendo*, $C \ A \ C \ B$ \ 3

PROPOSITION 5

Of two unequal magnitudes, the greater has a greater ratio to a third magnitude than the less has, and the same magnitude has a greater ratio to the less of two magnitudes than it has to the greater

First, let A be $> B$,
then shall $A \cdot C$ be $> B \cdot C$.

Since $A > B$, it will be possible to find m such that mA exceeds mB by a magnitude greater than C ;

hence if mA lies between nC and $(n+1)C$, $mB < nC$

and if $mA = nC$, then $mB < nC$;

$\therefore A : C > B : C$ Def 6.

Secondly, let B be $< A$;
then shall $C : B$ be $> C : A$

For taking m and n as before,

$nC > mB$, while nC is not $> mA$,

$C : B > C : A$ Def 6

PROPOSITION 6

Magnitudes which have the same ratio to the same magnitude are equal to one another, and those to which the same magnitude has the same ratio are equal to one another

First, let $A : C = B : C$,
then shall $A = B$

For if $A > B$, then $A : C > B : C$,

and if $B > A$, then $B : C > A : C$, v 5

which contradict the hypothesis,

$A = B$

Secondly, let $C : A :: C : B$,
 then shall $A = B$
 Because $C : A :: C : B$,
, invertendo, $A : C :: B : C$,
 $A = B$,
 by the first part of the proof

v 3

PROPOSITION 7

That magnitude which has a greater ratio than another has to the same magnitude is the greater of the two, and that magnitude to which the same has a greater ratio than it has to another magnitude is the less of the two

First, let $A : C$ be $> B : C$,
 then shall A be $> B$

For if $A = B$, then $A : C :: B : C$,
 which is contrary to the hypothesis v 4

And if $A < B$, then $A : C < B : C$,
 which is contrary to the hypothesis, v 5

$$A > B$$

Secondly, let $C : A$ be $> C : B$,
 then shall A be $< B$

For if $A = B$, then $C : A :: C : B$,
 which is contrary to the hypothesis v 4

And if $A > B$, then $C : A < C : B$,
 which is contrary to the hypothesis, v 5.

$$A < B$$

PROPOSITION 8

Magnitudes have the same ratio to one another which their equimultiples have.

Let A, B be two magnitudes,
then shall $A : B :: mA : mB$

If p, q be any two whole numbers,
then $m \cdot pA \geq$ or $< m \cdot qB$
according as $pA \geq$ or $< qB$

But $m \cdot pA = p \cdot mA$, and $m \cdot qB = q \cdot mB$,
 $p \cdot mA \geq$ or $< q \cdot mB$
according as $pA \geq$ or $< qB$,

$A : B :: mA : mB$ Def 4

COR Let A B C D

Then since $A : B :: mA : mB$,
and $C : D :: nC : nD$,
 $mA : mB :: nC : nD$

v 1

PROPOSITION 9

If two ratios are equal, and any equimultiples' of the antecedents and also of the consequents are taken, the multiple of the first antecedent has to that of its consequent the same ratio as the multiple of the other antecedent has to that of its consequent

Let A B C D,
then shall $mA : nB :: mC : nD$

Let p, q be any two whole numbers,
then because $A : B :: C : D$,

$pm \cdot C \geq$ or $< qn \cdot D$
according as $pm \cdot A \geq$ or $< qn \cdot B$, Def 4

that is, $p \cdot mC \geq$ or $< q \cdot nD$,
according as $p \cdot mA \geq$ or $< q \cdot nB$,

$mA : nB :: mC : nD$. Def 4

PROPOSITION 10

If four magnitudes of the same kind are proportionals, the first is greater than, equal to, or less than the third, according as the second is greater than, equal to, or less than the fourth

Let A, B, C, D be four magnitudes of the same kind such that

$$\begin{array}{rcl}
 & A & B & C & D, \\
 & \text{then } A > \text{ or } < C \\
 & \text{according as } B > \text{ or } < D \\
 \text{If } B > D, & \text{then } A & B < A & D, & \text{v 5} \\
 & \text{but } A & B & C < D, \\
 & C & D < A & D, \\
 & A & D > C & D, \\
 & A > C & & \text{v 7}
 \end{array}$$

Similarly it may be shewn that

$$\begin{array}{l}
 \text{if } B < D, \text{ then } A < C, \\
 \text{and if } B = D, \text{ then } A = C
 \end{array}$$

PROPOSITION 11

If four magnitudes of the same kind are proportionals, they are also proportionals when taken alternately

Let A, B, C, D be four magnitudes of the same kind such that

$$\begin{array}{rcl}
 & A & B & C & D, \\
 \text{then shall} & A & C & B & D \\
 & \text{Because } A & B & mA & mB, & \text{v 8} \\
 & \text{and } C & D & mC & nD, \\
 & mA & mB & nC & nD & \text{v 1} \\
 & mA > \text{ or } < nC \\
 & \text{according as } mB > \text{ or } < nD & \text{v 10} \\
 & \text{and } m \text{ and } n \text{ are any whole numbers,} \\
 & A & C & B & D & \text{Def 4}
 \end{array}$$

NOTE This inference is usually referred to as *alternando* or *alternately*

PROPOSITION 12.

If any number of magnitudes of the same kind are proportionals, as one of the antecedents is to its consequent, so is the sum of the antecedents to the sum of the consequents

Let A, B, C, D, E, F, be magnitudes of the same kind such that

A B C D E F ,
then shall A B A + C + E + B + D + F +

Because A B . C D E F : ,
according as $mA > \text{or} < nB$,
so is $mC > \text{or} < nD$,
and $mE > \text{or} < nF$,

so is $mA + mC + mE + > \text{or} < nB + nD + nF +$
or $m(A + C + E +) > \text{or} < n(B + D + F +)$,
and m and n are any whole numbers,

A : B A + C + E + B + D + F + Def 4

NOTE This inference is usually referred to as addendo

PROPOSITION 13

If four magnitudes are proportionals, the sum or difference of the first and second is to the second as the sum or difference of the third and fourth is to the fourth

Let A : B C D ,
then shall A + B B C + D D ,
and A ~ B : B C ~ D D

If m be any whole number, it is possible to find another number n such that $mA = nB$, or lies between nB and $(n + 1)B$,

$mA + mB = mB + nB$, or lies between $mB + nB$ and
 $mB + (n + 1)B$

But $mA + mB = m(A + B)$, and $mB + nB = (m + n)B$,
 $m(A + B) = (m + n)B$, or lies between $(m + n)B$
 and $(m + n + 1)B$

Also because $A \quad B \quad C \quad D$,
 $mC = nD$, or lies between nD and $(n + 1)D$, *Def 4*
 $m(C + D) = (m + n)D$ or lies between $(m + n)D$ and
 $(m + n + 1)D$,

that is, the multiples of $C + D$ are distributed among those
 of D in the same way as the multiples of $A + B$ among
 those of B ,

$A + B \quad B \quad C + D \quad D$

In the same way it may be proved that

$A - B \quad B \quad C - D \quad D$,

or $B - A \quad B \quad D - C \quad D$,

according as A is $>$ or $<$ B

NOTE These inferences are referred to as *componendo* and *divi-*
dendo respectively

PROPOSITION 14

If there are two sets of magnitudes, such that the first is to the second of the first set as the first to the second of the other set, and the second to the third of the first set as the second to the third of the other, and so on to the last magnitude then the first is to the last of the first set as the first to the last of the other

First, let there be three magnitudes A, B, C , of one set
 and three, P, Q, R , of another set,

and let $A \quad B \quad P \quad Q$,

and $B \quad C \quad Q \quad R$,

then shall $A \quad C \quad P \quad R$

Because $A \quad B \quad P \quad Q$,

$mA \quad mB \quad mP \quad mQ$,

v 8, *Cor*

and because $B \quad C \quad Q \quad R$,

$mB \quad nC \quad mQ \quad nR$,

v 9

, *invertendo*,

$nC \quad mB \quad nR \quad mQ$

v 3

Now, if $mA > nC$,
 then $mA \quad mB > nC \quad mB$, v 5
 $mP \quad mQ > nR \quad mQ$,
 and $mP > nR$ v 7

Similarly it may be shewn that $mP = oI < nR$,
 according as $mA = oI < nC$,

A . C P R *Def* 4

Secondly, let there be any number of magnitudes, A, B, C, L, M, of one set, and the same number P, Q, R, Y, Z, of another set, such that

A B P Q,
 B C Q R,

L M Y Z,

then shall A M P Z

For A C P R,
 and C D R S,

*Proved

that is, P is the mean proportional between C and Y

P = D,

A B C D

BOOK VI

DEFINITIONS

1 Two rectilineal figures are said to be equiangular when the angles of the first, taken in order, are equal respectively to those of the second, taken in order. Each angle of the first figure is said to correspond to the angle to which it is equal in the second figure, and sides adjacent to corresponding angles are called corresponding sides.

2 Rectilineal figures are said to be similar when they are equiangular and have the sides about the equal angles proportionals, the corresponding sides being homologous.

[See Def 5, page 288]

Thus the two quadrilaterals ABCD, EFGH are similar if the angles at A, B, C, D are respectively equal to those at E, F, G, H, and if the following proportions hold

AB	BC	EF	FG,
BC	CD	FG	GH,
CD	DA	GH	HE,
DA	AB	HE	EF

3 Two figures are said to have their sides about two of their angles reciprocally proportional when a side of the first is to a side of the second as the remaining side of the second is to the remaining side of the first.

4 A straight line is said to be divided in extreme and mean ratio when the whole is to the greater segment as the greater segment is to the less

5 Two similar rectilineal figures are said to be similarly situated with respect to two of their sides when these sides are homologous. ✓

PROPOSITION 1 THEOREM

The areas of triangles of the same altitude are to one another as their bases

Let ABC, ACD be two triangles of the same altitude, namely the perpendicular from A to BD

then shall the $\triangle ABC$ the $\triangle ACD$ BC CD

Produce BD both ways,

and from CB produced cut off any number of parts BG, GH, each equal to BC,

and from CD produced cut off any number of parts DK, KL, LM each equal to CD

Join AH, AG, AK, AL, AM

Then the \triangle^s ABC, ABG, AGH are equal in area, for they are of the same altitude and stand on the equal bases CB, BG, GH, I 38

the $\triangle AHC$ is the same multiple of the $\triangle ABC$ that HC is of BC,

Similarly the $\triangle ACM$ is the same multiple of ACD that CM is of CD

And if $HC = CM$,

the $\triangle AHC =$ the $\triangle ACM$, I 38

and if HC is greater than CM,

the $\triangle AHC$ is greater than the $\triangle ACM$, I 38, Cor

and if HC is less than CM,

the $\triangle AHC$ is less than the $\triangle ACM$ I 38, Cor

Now since there are four magnitudes, namely, the \triangle^s ABC, ACD, and the bases BC, CD, and of the antecedents, any equimultiples have been taken, namely, the $\triangle AHC$

and the base HC , and of the consequents, any equimultiples have been taken, namely the $\triangle ACM$ and the base CM , and since it has been shewn that the $\triangle AHG$ is greater than, equal to, or less than the $\triangle ACM$, according as HC is greater than, equal to, or less than CM ,

\therefore the four original magnitudes are proportionals, v *Def* 4 that is,
the $\triangle ABC$: the $\triangle ACD$. the base BC : the base CD Q.E.D.

COROLLARY *The areas of parallelograms of the same altitude are to one another as their bases*

Let EC , CF be par^m of the same altitude,
then shall the par^m EC : the par^m CF $BC : CD$.

Join BA , AD

Then the $\triangle ABC$. the $\triangle ACD$. $BC : CD$, *Proved*
but the par^m EC is double of the $\triangle ABC$,
and the par^m CF is double of the $\triangle ACD$,
the par^m EC : the par^m CF . $BC : CD$ v. 8

NOTE Two straight lines are cut proportionally when the segments of one line are in the same ratio as the corresponding segments of the other [See definition, page 181]

Thus AB and CD are cut proportionally at X and Y , if

$$AX \cdot XB = CY \cdot YD$$

And the same definition applies equally whether X and Y divide AB , CD internally as in Fig 1 or externally as in Fig. 2

PROPOSITION 2 THEOREM

If a straight line be drawn parallel to one side of a triangle, it shall cut the other sides, or those sides produced, proportionally

Conversely, if the sides or the sides produced be cut proportionally, the straight line which joins the points of section, shall be parallel to the remaining side of the triangle

Let XY be drawn par^l to BC , one of the sides of the $\triangle ABC$
then shall

$$BX : XA :: CY : YA$$

Join BY, CX

Then the $\triangle BXY =$ the $\triangle CXY$, being on the same base XY
and between the same parallels XY, BC , I 37
and AXY is another triangle,

the $\triangle BXY$	the $\triangle AXY$	the $\triangle CXY$	the $\triangle AXY$	v 4
But the $\triangle BXY$	the $\triangle AXY$	$BX : XA$,		VI 1
and the $\triangle CXY$	the $\triangle AXY$	$CY : YA$,		
		$BX : XA :: CY : YA$		v 1

Conversely, let $BX : XA :: CY : YA$, and let XY be joined
then shall XY be par^l to BC

As before, join BY, CX

By hypothesis $BX : XA :: CY : YA$,

but $BX : XA$	the $\triangle BXY$	the $\triangle AXY$,	VI 1
and $CY : YA$	the $\triangle CXY$	the $\triangle AXY$,	

the $\triangle BXY$	the $\triangle AXY$	the $\triangle CXY$	the $\triangle AXY$	v 1
		the $\triangle BXY =$ the $\triangle CXY$,		v 6

and they are triangles on the same base and on the same side of it

XY is par^l to BC

I 39

Q.E.D.

EXERCISES

1 Shew that every quadrilateral is divided by its diagonals into four triangles proportional to each other.

2 *If any two straight lines are cut by three parallel straight lines, they are cut proportionally.*

3 From a point E in the common base of two triangles ACB, ADB, straight lines are drawn parallel to AC, AD, meeting BC, BD at F, G. shew that FG is parallel to CD.

4 In a triangle ABC the straight line DEF meets the sides BC, CA, AB at the points D, E, F respectively, and it makes equal angles with AB and AC prove that

$$BD : CD :: BF : CE$$

5 If the bisector of the angle B of a triangle ABC meets AD at right angles, shew that a line through D parallel to BC will bisect AC

6. From B and C, the extremities of the base of a triangle ABC, lines BE, CF are drawn to the opposite sides so as to intersect on the median from A: shew that EF is parallel to BC

7. From P, a given point in the side AB of a triangle ABC, draw a straight line to AC produced, so that it will be bisected by BC

8 Find a point within a triangle such that, if straight lines be drawn from it to the three angular points, the triangle will be divided into three equal triangles

PROPOSITION 3 THEOREM

If the vertical angle of a triangle be bisected by a straight line which cuts the base, the segments of the base shall have to one another the same ratio as the remaining sides of the triangle.

Conversely, if the base be divided so that its segments have to one another the same ratio as the remaining sides of the triangle have, the straight line drawn from the vertex to the point of section shall bisect the vertical angle

In the $\triangle ABC$ let the $\angle BAC$ be bisected by AX , which meets the base at X ,
then shall $BX \quad XC \quad BA \quad AC$

Through C draw CE par^l to XA , to meet BA produced at E I 31

Then because XA and CE are par^l,
the $\angle BAX =$ the int opp $\angle AEC$, I 29
and the $\angle XAC =$ the alt $\angle ACE$ I 29
But the $\angle BAX =$ the $\angle XAC$, Hyp
∴ the $\angle AEC =$ the $\angle ACE$,
 $AC = AE$ I 6

Again, because XA is par^l to CE , a side of the $\triangle BCE$,
 $BX \quad XC \quad BA \quad AE$, VI 2
that is, $BX \quad XC \quad BA \quad AC$

Conversely, let $BX \cdot XC = BA \cdot AC$, and let AX be joined.
then shall the $\angle BAX = \angle XAC$.

For, with the same construction as before,
because XA is *par*^l to CE , a side of the $\triangle BCE$,

$$\therefore BX \cdot XC = BA \cdot AE \quad \text{VI. 2}$$

But by hypothesis $BX \cdot XC = BA \cdot AC$,

$$\therefore BA \cdot AE :: BA \cdot AC; \quad \text{V. 1.}$$

$$\therefore AE = AC,$$

$$\therefore \text{the } \angle ACE = \text{the } \angle AEC \quad \text{I. 5.}$$

But because XA is *par*^l to CE ,

$$\therefore \text{the } \angle XAC = \text{the alt } \angle ACE \quad \text{I. 29.}$$

and the ext. $\angle BAX = \text{the int opp. } \angle AEC$; I. 29.

$$\therefore \text{the } \angle BAX = \text{the } \angle XAC.$$

Q E D.

EXERCISES

1. The side BC of a triangle ABC is bisected at D , and the angles ADB , ADC are bisected by the straight lines DE , DF , meeting AB , AC at E , F respectively. shew that EF is parallel to BC .

2. Apply Proposition 3 to trisect a given finite straight line.

3. If the line bisecting the vertical angle of a triangle be divided into parts which are to one another as the base to the sum of the sides, the point of division is the centre of the inscribed circle

4. $ABCD$ is a quadrilateral. shew that if the bisectors of the angles A and C meet in the diagonal BD , the bisectors of the angles B and D will meet on AC

5. Construct a triangle having given the base, the vertical angle, and the ratio of the remaining sides.

6. Employ this proposition to shew that the bisectors of the angles of a triangle are concurrent

7. AB is a diameter of a circle, CD is a chord at right angles to it, and E any point in CD . AE and BE are drawn and produced to cut the circle in F and G . shew that the quadrilateral $CFDG$ has any two of its adjacent sides in the same ratio as the remaining two

PROPOSITION A THEOREM

If one side of a triangle be produced, and the exterior angle so formed be bisected by a straight line which cuts the base produced, the segments between the bisector and the extremities of the base shall have to one another the same ratio as the remaining sides of the triangle have

Conversely, if the segments of the base produced have to one another the same ratio as the remaining sides of the triangle have, the straight line drawn from the vertex to the point of section shall bisect the exterior vertical angle

In the $\triangle ABC$ let BA be produced to F, and let the exterior $\angle CAF$ be bisected by AX which meets the base produced at X
then shall

$$BX : XC :: BA : AC$$

Through C draw CE par^l to AX, I 31
and let CE meet BA at E

Then because AX and CE are par^l,
the ext $\angle FAX =$ the int opp $\angle AEC$,
and the $\angle XAC =$ the alt. $\angle ACE$ I 29

But the $\angle FAX =$ the $\angle XAC$, Hyp

the $\angle AEC =$ the $\angle ACE$,
 $AC = AE$ I 6

Again, because XA is par^l to CE, a side of the $\triangle BCE$,
Constr
 $BX : XC :: BA : AE$, VI 2

that is, $BX : XC :: BA : AC$

Conversely, let $BX \cdot XC = BA \cdot AC$, and let AX be joined
then shall the $\angle FAX =$ the $\angle XAC$

For, with the same construction as before,
because AX is par^l to CE , a side of the $\triangle BCE$,

$$\therefore BX \cdot XC = BA \cdot AE \quad \text{VI } 2$$

But by hypothesis $BX \cdot XC = BA \cdot AC$,

$$\therefore BA \cdot AE = BA \cdot AC, \quad \text{V. } 1.$$

$$\therefore AE = AC,$$

$$\therefore \text{the } \angle ACE = \text{the } \angle AEC. \quad \text{I } 5.$$

But because AX is par^l to CE ,

$$\therefore \text{the } \angle XAC = \text{the alt } \angle ACE,$$

$$\text{and the ext } \angle FAX = \text{the int opp } \angle AEC, \quad \text{I. } 29$$

$$\text{the } \angle FAX = \text{the } \angle XAC. \quad \text{Q E D}$$

Propositions 3 and A may be both included in one enunciation as follows

If the interior or exterior vertical angle of a triangle be bisected by a straight line which also cuts the base, the base shall be divided internally or externally into segments which have the same ratio as the sides of the triangle

Conversely, if the base be divided internally or externally into segments which have the same ratio as the sides of the triangle, the straight line drawn from the point of division to the vertex will bisect the interior or exterior vertical angle.

EXERCISES

1 In the circumference of a circle of which AB is a diameter, a point P is taken, straight lines PC , PD are drawn equally inclined to AP and on opposite sides of it, meeting AB in C and D ,
shew that $AC \cdot CB = AD \cdot DB$

2 From a point A straight lines are drawn making the angles BAC , CAD , DAE , each equal to half a right angle, and they are cut by a straight line $BCDE$, which makes BAE an isosceles triangle: shew that BC or DE is a mean proportional between BE and CD .

3 By means of Propositions 3 and A, prove that the straight lines bisecting one angle of a triangle internally, and the other two externally, are concurrent

PROPOSITION 4 THEOREM

If two triangles be equiangular to one another, the sides about the equal angles shall be proportionals, those sides which are opposite to equal angles being homologous

Let the $\triangle ABC$ be equiangular to the $\triangle DCE$, having the $\angle ABC$ equal to the $\angle DCE$, the $\angle BCA$ equal to the $\angle CED$, and consequently the $\angle CAB$ equal to the $\angle EDC$ I 32 then shall the sides about these equal angles be proportionals, namely

$$\begin{array}{cccc} AB & BC & DC & CE, \\ BC & CA & CE & ED, \\ \text{and } AB & AC & DC & DE \end{array}$$

Let the $\triangle DCE$ be placed so that its side CE may be contiguous to BC , and in the same straight line with it

Then because the $\angle^s ABC, ACB$ are together less than two rt angles, I 17

and the $\angle ACB = \text{the } \angle DEC$,

the $\angle^s ABC, DEC$ are together less than two rt angles, Hyp

BA and ED will meet if produced Ax 12

Let them be produced and meet at F

Then because the $\angle ABC = \text{the } \angle DCE$,

BF is par^l to CD ,

I 28

and because the $\angle ACB = \text{the } \angle DEC$,

Hyp.

AC is par^l to FE ,

I 28

$FACD$ is a par^m,

$AF = CD$, and $AC = FD$

I 34

Again, because CD is par^l to BF, a side of the $\triangle EBF$,

$$\therefore BC : CE :: FD : DE; \quad \text{VI. 2.}$$

but $FD = AC$;

$$\therefore BC : CE :: AC : DE;$$

and, *alternately*, $BC : CA :: CE : ED.$ v. 11

Again, because AC is par^l to FE, a side of the $\triangle FBE$,

$$\therefore BA : AF :: BC : CE, \quad \text{VI. 2.}$$

but $AF = CD$;

$$\therefore BA : CD :: BC : CE,$$

and, *alternately* $AB : BC :: DC : CE.$ v. 11.

Also $BC : CA :: CE : ED.$ *Proved.*

\therefore , *ex æquali*, $AB : AC :: DC : DE.$ v. 14.

Q.E.D.

{For Alternative Proof see Page 320 }

EXERCISES.

1. If one of the parallel sides of a trapezium is double the other, shew that the diagonals intersect one another at a point of trisection.

2. In the side AC of a triangle ABC any point D is taken. shew that if AD, DC, AB, BC are bisected in E, F, G, H respectively, then EG is equal to HF.

3. AB and CD are two parallel straight lines; E is the middle point of CD, AC and BE meet at F, and AE and BD meet at G: shew that FG is parallel to AB

4. ABCDE is a regular pentagon, and AD and BE intersect in F: shew that $AF : AE :: AE : AD.$

5. In the figure of 1. 43 shew that EH and GF are parallel, and that FH and GE will meet on CA produced.

6. Chords AB and CD of a circle are produced towards B and D respectively to meet in the point E, and through E, the line EF is drawn parallel to AD to meet CB produced in F. Prove that EF is a mean proportional between FB and FC.

PROPOSITION 5 THEOREM

If the sides of two triangles, taken in order about each of their angles, be proportionals, the triangles shall be equiangular to one another, having those angles equal which are opposite to the homologous sides

Let the \triangle^s ABC, DEF have their sides proportionals, so that

$$AB : BC :: DE : EF,$$

$$BC : CA :: EF : FD,$$

and consequently, *ex æquali*,

$$AB : CA :: DE : FD$$

Then shall the triangles be equiangular

At E in FE make the $\angle FEG$ equal to the $\angle ABC$,

and at F in EF make the $\angle EFG$ equal to the $\angle BCA$, I 23

then the remaining $\angle EGF =$ the remaining $\angle BAC$ I 32

the $\triangle GEF$ is equiangular to the $\triangle ABC$,

$$GE : EF :: AB : BC$$

VI 4

$$\text{But } AB : BC :: DE : EF,$$

IIyp

$$GE : EF :: DE : EF,$$

V 1.

$$GE = DE.$$

Similarly $GF = DF$

Then in the triangles GEF, DEF

Because { $GE = DE$,
 $GF = DF$,
 and EF is common,
 the $\angle GEF =$ the $\angle DEF$,
 and the $\angle GFE =$ the $\angle DFE$,
 and the $\angle EGF =$ the $\angle EDF$

I 8

But the $\angle GEF =$ the $\angle ABC$,

the $\angle DEF =$ the $\angle ABC$

Constr

Similarly, the $\angle EFD =$ the $\angle BCA$,

. the remaining $\angle FDE =$ the remaining $\angle CAB$, I. 32.
that is, the $\triangle DEF$ is equiangular to the $\triangle ABC$

Q E D

PROPOSITION 6 THEOREM

If two triangles have one angle of the one equal to one angle of the other, and the sides about the equal angles proportionals, the triangles shall be similar.

In the $\triangle^s ABC, DEF$ let the $\angle BAC =$ the $\angle EDF$,
and let $BA \cdot AC : ED \cdot DF$

Then shall the $\triangle^s ABC, DEF$ be similar

At D in FD make the $\angle FDG$ equal to one of the $\angle^s EDF, BAC$.
at F in DF make the $\angle DFG$ equal to the $\angle ACB$, I. 23
. the remaining $\angle FGD =$ the remaining $\angle ABC$ I. 32

Then the $\triangle ABC$ is equiangular to the $\triangle GDF$,

$$. BA \cdot AC = GD \cdot DF.$$

VI. 4.

$$\text{But } BA \cdot AC = ED \cdot DF,$$

Hyp

$$GD : DF : ED : DF,$$

$$. GD = ED.$$

Then in the $\triangle^s GDF, EDF$,

$$GD = ED,$$

Because {

and DF is common,

and the $\angle GDF =$ the $\angle EDF$,

Constr

the $\triangle^s GDF, EDF$ are equal in all respects, I. 4
so that the $\triangle EDF$ is equiangular to the $\triangle GDF$;

but the $\triangle GDF$ is equiangular to the $\triangle BAC$, Constr.

. the $\triangle EDF$ is equiangular to the $\triangle BAC$,

their sides about the equal angles are proportionals, VI. 4

that is, the $\triangle^s ABC, DEF$ are similar

Q E D.

NOTE 1 From Definition 2 it is seen that *two* conditions are necessary for similarity of rectilineal figures, namely (1) the figures must be equiangular, and (2) the sides about the equal angles must be proportionals. In the case of *triangles* we learn from Props 4 and 5 that each of these conditions follows from the other: this however is not necessarily the case with rectilineal figures of more than three sides.

NOTE 2 We have given Euclid's demonstrations of Propositions 4, 5, 6, but these propositions also admit of easy proof by the method of superposition.

As an illustration, we will apply this method to Proposition 4

PROPOSITION 4 [ALTERNATIVE PROOF]

If two triangles be equiangular to one another, the sides about the equal angles shall be proportionals, those sides which are opposite to equal angles being homologous

Let the $\triangle ABC$ be equiangular to the $\triangle DEF$, having the $\angle ABC$ equal to the $\angle DEF$, the $\angle BCA$ equal to the $\angle EFD$, and consequently the $\angle CAB$ equal to the $\angle FDE$ I 32

then shall the sides about these equal angles be proportionals

Apply the $\triangle ABC$ to the $\triangle DEF$, so that B falls on E and BA along ED

then BC will fall along EF, since the $\angle ABC = \angle DEF$ *Hyp*

Let G and H be the points in ED and EF, on which A and C fall

Join GH

Then because the $\angle EGH = \angle EDF$, *Hyp*

GH is par^l to DF

	DG	GE	FH	HE,
, componendo,	DE	GE	FE	HE,
, alternately,	DE	FE	GE	HE,
that is,	DE	EF	AB	BC

v 13

v 11

Similarly by applying the $\triangle ABC$ to the $\triangle DEF$, so that the point C may fall on F, it may be proved that

	EF	FD	BC	CA
, ex æquali,	DE	DF	AB	AC

✓ PROPOSITION 7. THEOREM

If two triangles have one angle of the one equal to one angle of the other and the sides about one other angle in each proportional, so that the sides opposite to the equal angles are homologous, then the third angles are either equal or supplementary; and in the former case the triangles are similar

Let ABC , DEF be two triangles having the $\angle ABC$ equal to the $\angle DEF$, and the sides about the angles at A and D proportional, so that

$$BA : AC :: ED : DF,$$

then shall the \angle^s ACB , DFE be either equal or supplementary, and in the former case the triangles shall be similar

If the $\angle BAC =$ the $\angle EDF$,

then the $\angle BCA =$ the $\angle EFD$, I 32

and the Δ^s are equiangular and therefore similar. VI 4

But if the $\angle BAC$ is not equal to the $\angle EDF$, one of them must be the greater

Let the $\angle EDF$ be greater than the $\angle BAC$

At D in ED make the $\angle EDF'$ equal to the $\angle BAC$ I. 23

Then the Δ^s BAC , EDF' are equiangular, Constr

$$\therefore BA : AC :: ED : DF', \quad \text{VI 4}$$

$$\text{but } BA : AC :: ED : DF, \quad \text{Hyp}$$

$$\therefore ED : DF :: ED : DF', \quad \text{V 1}$$

$$\therefore DF = DF',$$

$$\therefore \text{the } \angle DFF' = \text{the } \angle DF'E. \quad \text{I 5}$$

But the \angle^s $DF'E$, $DF'E$ are supplementary, I 13

\therefore the \angle^s DFF' , $DF'E$ are supplementary
that is, the \angle^s DFE , ACB are supplementary

Q E D

COROLLARIES TO PROPOSITION 7

Three cases of this theorem deserve special attention

It has been proved that if the angles ACB , DFE are not *supplementary*, they are *equal*

and we know that of angles which are supplementary and unequal, one must be acute and the other obtuse

Hence, in addition to the hypothesis of this theorem,

- (i) If the angles ACB , DFE , opposite to the two homologous sides AB , DE are both acute, both obtuse, or if one of them is a right angle,
it follows that these angles are equal,
and therefore the triangles are similar
- (ii) If the two given angles are right angles or obtuse angles,
it follows that the angles ACB , DFE must be both acute,
and therefore equal, by (i)
so that the triangles are similar
- (iii) If in each triangle the side opposite the given angle is not less than the other given side, that is, if AC and DF are not less than AB and DE respectively, then
the angles ACB , DFE cannot be greater than the angles ABC , DEF , respectively,
therefore the angles ACB , DFE , are both acute,
hence, as above, they are equal,
and the triangles ABC , DEF similar

EXERCISES

ON PROPOSITIONS 1 TO 7

1 Shew that the diagonals of a trapezium cut one another in the same ratio.

2 If three straight lines drawn from a point cut two parallel straight lines in A, B, C and P, Q, R respectively, prove that
 $AB \cdot BC = PQ \cdot QR$.

3 From a point O, a tangent OP is drawn to a given circle, and OQR is drawn cutting it in Q and R; shew that
 $OQ \cdot OP = OP \cdot OR$

4. If two triangles are on equal bases and between the same parallels, any straight line parallel to their bases will cut off equal areas from the two triangles

5 If two straight lines PQ, XY intersect in a point O, so that $PO \cdot OX = YO \cdot OQ$, prove that P, X, Q, Y are concyclic

6 On the same base and on the same side of it two equal triangles ACB, ADB are described, AC and BD intersect in O, and through O lines parallel to DA and CB are drawn meeting the base in E and F. Shew that $AE = BF$

7 BD, CD are perpendicular to the sides AB, AC of a triangle ABC, and CE is drawn perpendicular to AD, meeting AB in E shew that the triangles ABC, ACE are similar

8 AC and BD are drawn perpendicular to a given straight line CD from two given points A and B, AD and BC intersect in E, and EF is perpendicular to CD shew that AF and BF make equal angles with CD

9. ABCD is a parallelogram, P and Q are points in a straight line parallel to AB, PA and QB meet at R, and PD and QC meet at S. shew that RS is parallel to AD

10 In the sides AB, AC of a triangle ABC two points D, E are taken such that BD is equal to CE, if DE, BC produced meet at F, shew that $AB : AC = EF : DF$.

11. Find a point the perpendiculars from which on the sides of a given triangle shall be in a given ratio.

PROPOSITION 8 THEOREM

In a right-angled triangle if a perpendicular be drawn from the right angle to the hypotenuse, the triangles on each side of it are similar to the whole triangle and to one another

Let ABC be a triangle right-angled at A , and let AD be perp to BC
 then shall the $\triangle^s DBA, DAC$ be similar to the $\triangle ABC$ and to one another

In the $\triangle^s DBA, ABC$,
 the $\angle BDA =$ the $\angle BAC$, being rt angles,
 and the $\angle ABC$ is common to both,
 the remaining $\angle BAD =$ the remaining $\angle BCA$, $\text{I } 32$
 that is, the $\triangle^s DBA, ABC$ are equiangular,
 they are similar VI 4

In the same way it may be proved that the $\triangle^s DAC, ABC$ are similar

Hence the $\triangle^s DBA, DAC$, being equiangular to the same $\triangle ABC$, are equiangular to one another,
 they are similar VI 4

Q E D

COROLLARY Because the $\triangle^s BDA, ADC$ are similar,
 $\frac{BD}{DA} = \frac{DA}{DC}$,
 and because the $\triangle^s CBA, ABD$ are similar,
 $\frac{CB}{BA} = \frac{BA}{BD}$,
 and because the $\triangle^s BCA, ACD$ are similar,
 $\frac{BC}{CA} = \frac{CA}{CD}$

EXERCISES

1 Prove that the hypotenuse is to one side as the second side is to the perpendicular

2 Shew that the radius of a circle is a mean proportional between the segments of any tangent between its point of contact and a pair of parallel tangents

DEFINITION. A less magnitude is said to be a submultiple of a greater, when the less is contained an *exact* number of times in the greater [Book v. Def 2]

PROPOSITION 9 PROBLEM

From a given straight line to cut off any required submultiple

Let AB be the given straight line

It is required to cut off a certain submultiple from AB

From A draw a straight line AG of indefinite length making any angle with AB

In AG take any point D, and, by cutting off successive parts each equal to AD, make AE to contain AD as many times as AB contains the required submultiple.

Join EB

Through D draw DF par^l to EB, meeting AB in F

Then shall AF be the required submultiple.

Because DF is par^l to EB, a side of the $\triangle AEB$,

$$\therefore \frac{BF}{FA} = \frac{ED}{DA}, \quad \text{VI. 2.}$$

$$\therefore, \text{componendo, } \frac{BA}{AF} = \frac{EA}{AD} \quad \text{v 13.}$$

But AE contains AD the required number of times, Constr

. AB contains AF the required number of times,
that is, AF is the required submultiple Q E F.

EXERCISES

1. Divide a straight line into five equal parts
2. Give a geometrical construction for cutting off two-sevenths of a given straight line

PROPOSITION 10 PROBLEM

To divide a straight line similarly to a given divided straight line

Let AB be the given straight line to be divided, and AC the given straight line divided at the points D and E

It is required to divide AB similarly to AC

Let AB, AC be placed so as to form any angle

Join CB

Through D draw DF par^l to CB, I 31

and through E draw EG par^l to CB,

and through D draw DHK par^l to AB

Then AB shall be divided at F and G similarly to AC

For by construction each of the figs FH, HB is a par^m,

DH = FG, and HK = GB I 34

Now since HE is par^l to KC, a side of the $\triangle DKC$,

KH : HD = CE : ED VI 2

But KH = BG, and HD = GF,

BG : GF = CE : ED v 1

Again, because FD is par^l to GE, a side of the $\triangle AGE$,

GF : FA = ED : DA, VI 2

and it has been shewn that

BG : GF = CE : ED,

, *ex aequali*, BG : FA = CE : DA v. 14

AB is divided similarly to AC Q E F

EXERCISE

Divide a straight line internally and externally in a given ratio Is this always possible?

PROPOSITION 11 PROBLEM.

To find a third proportional to two given straight lines

Let A, B be two given straight lines

It is required to find a third proportional to A and B.

Take two st lines DL, DK of indefinite length, containing any angle

from DL cut off DG equal to A, and GE equal to B,
and from DK cut off DH equal to B I 3

Join GH

Through E draw EF par^l to GH, meeting DK in F. I 31

Then shall HF be a thud proportional to A and B

Because GH is par^l to EF, a side of the $\triangle DEF$,

$\therefore DG : GE :: DH : HF$ VI 2

But $DG = A$, and GE, DH each $= B$, Constr

$A : B :: B : HF$,

that is, HF is a thud proportional to A and B

Q E F

EXERCISES

1 AB is a diameter of a circle, and through A any straight line is drawn to cut the circumference in C and the tangent at B in D shew that AC is a third proportional to AD and AB

2 ABC is an isosceles triangle having each of the angles at the base double of the vertical angle BAC; the bisector of the angle BCA meets AB at D Shew that AB, BC, BD are three proportionals

3 Two circles intersect at A and B, and at A tangents are drawn, one to each circle, to meet the circumferences at C and D shew that if CB, BD are joined, BD is a third proportional to CB, BA.

PROPOSITION 12 PROBLEM

To find a fourth proportional to three given straight lines

Let A, B, C be the three given straight lines
It is required to find a fourth proportional to A, B, C

Take two straight lines DL, DK containing any angle
from DL cut off DG equal to A , GE equal to B ,
and from DK cut off DH equal to C I 3

Join GH

Through E draw EF par^l to GH I 31.
Then shall HF be a fourth proportional to A, B, C

Because GH is par^l to EF , a side of the $\triangle DEF$,

$$\frac{DG}{GE} = \frac{DH}{HF} \quad \text{VI 2}$$

But $DG = A$, $GE = B$, and $DH = C$, Constr

$$\frac{A}{B} = \frac{C}{HF},$$

that is, HF is a fourth proportional to A, B, C

Q E F

EXERCISES

1 If from D , one of the angular points of a parallelogram $ABCD$, a straight line is drawn meeting AB at E and CB at F , shew that CF is a fourth proportional to EA, AD , and AB

2 In a triangle ABC the bisector of the vertical angle BAC meets the base at D and the circumference of the circumscribed circle at E shew that BA, AD, EA, AC are four proportionals

3 From a point P tangents PQ, PR are drawn to a circle whose centre is C , and QT is drawn perpendicular to RC produced shew that QT is a fourth proportional to PR, RC , and RT

PROPOSITION 13 PROBLEM

To find a mean proportional between two given straight lines

Let AB, BC be the two given straight lines
It is required to find a mean proportional between them

Place AB, BC in a straight line, and on AC describe the semicircle ADC

From B draw BD at rt. angles to AC I 11.
Then shall BD be a mean proportional between AB and BC
Join AD, DC

Now the $\angle ADC$ being in a semicircle is a rt angle, III. 31
and because in the right-angled $\triangle ADC$, DB is drawn from
the rt angle perp to the hypotenuse,

\therefore the \triangle^s ABD, DBC are similar, VI. 8.

$$AB \cdot BD = BD \cdot BC,$$

that is, BD is a mean proportional between AB and BC.

Q E F.

EXERCISES

1. If from one angle A of a parallelogram a straight line be drawn cutting the diagonal in E and the sides in P, Q, shew that AE is a mean proportional between PE and EQ

2. A, B, C are three points in order in a straight line. find a point P in the straight line so that PB may be a mean proportional between PA and PC.

3 The diameter AB of a semicircle is divided at any point C, and CD is drawn at right angles to AB meeting the circumference in D, DO is drawn to the centre, and CE is perpendicular to OD. shew that DE is a third proportional to AO and DC

4 AC is the diameter of a semicircle on which a point B is taken so that BC is equal to the radius shew that AB is a mean proportional between BC and the sum of BC, CA

5 A is any point in a semicircle on BC as diameter, from D any point in BC a perpendicular is drawn meeting AB, AC, and the circumference in E, G, F respectively, shew that DG is a third proportional to DE and DF

6 Two circles touch externally, and a common tangent touches them at A and B prove that AB is a mean proportional between the diameters of the circles [See Ex 21, p 219]

7 If a straight line be divided in two given points, determine a third point such that its distances from the extremities may be proportional to its distances from the given points

8 AB is a straight line divided at C and D so that AB, AC, AD are in continued proportion, from A a line AE is drawn in any direction and equal to AC, shew that BC and CD subtend equal angles at E

9 In a given triangle draw a straight line parallel to one of the sides, so that it may be a mean proportional between the segments of the base

10 On the radius OA of a quadrant OAB, a semicircle ODA is described, and at A a tangent AE is drawn, from O any line ODFE is drawn meeting the circumferences in D and F and the tangent in E if DG is drawn perpendicular to OA, shew that OE, OF, OD, and OG are in continued proportion

11 From any point A, in the circumference of the circle ABE, as centre, and with any radius, a circle BDC is described cutting the former circle in B and C', from A any line AFE is drawn meeting the chord BC in F, and the circumferences BDC, ABE in D, E respectively shew that AD is a mean proportional between AF and AE

DEFINITION Two figures are said to have their sides about two of their angles reciprocally proportional, when a side of the first is to a side of the second as the remaining side of the second is to the remaining side of the first

[Book VI Def 3]

PROPOSITION 14 THEOREM.

Parallelograms which are equal in area, and which have one angle of the one equal to one angle of the other, have their sides about the equal angles reciprocally proportional.

Conversely, parallelograms which have one angle of the one equal to one angle of the other, and the sides about these angles reciprocally proportional, are equal in area.

Let the par^m AB, BC be of equal area, and have the $\angle DBF$ equal to the $\angle GBE$:
then shall the sides about these equal angles be reciprocally proportional,

that is, $DB \cdot BE = GB \cdot BF$

Place the par^m so that DB, BE may be in the same straight line,

\therefore FB, BG are also in one straight line I. 14

Complete the par^m FE

Then because the par^m AB = the par^m BC, Hyp
and FE is another par^m,

the par^m AB the par^m FE : the par^m BC the par^m FE,
but the par^m AB the par^m FE : DB BE, VI 1
and the par^m BC the par^m FE GB BF,

$\therefore DB \cdot BE = GB \cdot BF.$ v 1

Conversely, let the $\angle DBF$ be equal to the $\angle GBE$,
and let $DB \cdot BE = GB \cdot BF$

Then shall the par^m AB be equal in area to the par^m BC

For, with the same construction as before,

by hypothesis $DB : BE = GB : BF$,

but $DB \cdot BE =$ the par^m AB : the par^m FE, VI 1

and $GB \cdot BF =$ the par^m BC the par^m FE,

the par^m AB the par^m FE the par^m BC the par^m FE; v 1.
the par^m AB = the par^m BC

Q E D

PROPOSITION 15. THEOREM

Triangles which are equal in area, and which have one angle of the one equal to one angle of the other, have their sides about the equal angles reciprocally proportional

Conversely, triangles which have one angle of the one equal to one angle of the other, and the sides about these angles reciprocally proportional, are equal in area

Let the \triangle^s ABC, ADE be of equal area, and have the \angle CAB equal to the \angle EAD
then shall the sides of the triangles about these angles be reciprocally proportional,

that is, CA AD EA AB

Place the \triangle^s so that CA and AD may be in the same st line,
 \therefore BA, AE are also in one st line r 14

Join BD

Then because the \triangle CAB = the \triangle EAD, *Hyp*
and ABD is another triangle,

the \triangle CAB	the \triangle ABD	the \triangle EAD	the \triangle ABD,	
but the \triangle CAB	the \triangle ABD	CA AD,		v 1
and the \triangle EAD	the \triangle ABD .	EA AB,		
	CA AD	EA AB		v 1

Conversely, let the \angle CAB be equal to the \angle EAD,
and let CA AD EA AB

Then shall the \triangle CAB = \triangle EAD

For, with the same construction as before,

by hypothesis CA AD EA AB,

but CA AD the \triangle CAB the \triangle ABD, vi 1

and EA AB the \triangle EAD the \triangle ABD,

the \triangle CAB the \triangle ABD . the \triangle EAD the \triangle ABD, v 1
the \triangle CAB = the \triangle EAD q. l. d

EXERCISES.

ON PROPOSITIONS 11 AND 15

1 *Parallelograms which are equal in area and which have their sides reciprocally proportional, have their angles respectively equal*

2 *Triangles which are equal in area, and which have the sides about a pair of angles reciprocally proportional, have those angles equal or supplementary.*

3. AC, BD are the diagonals of a trapezium which intersect in O; if the side AB is parallel to CD, use Prop 15 to prove that the triangle AOD is equal to the triangle BOC.

4. From the extremities A, B of the hypotenuse of a right-angled triangle ABC lines AE, BD are drawn perpendicular to AB, and meeting BC and AC produced in E and D respectively employ Prop. 15 to shew that the triangles ABC, EOD are equal in area

5 On AB, AC, two sides of any triangle, squares are described externally to the triangle. If the squares are ABDE, ACFG, shew that the triangles DAG, FAE are equal in area

6. ABCD is a parallelogram, from A and C any two parallel straight lines are drawn meeting DC and AB in E and F respectively; EG, which is parallel to the diagonal AC, meets AD in G. shew that the triangles DAF, GAB are equal in area

7. Describe an isosceles triangle equal in area to a given triangle and having its vertical angle equal to one of the angles of the given triangle

8. Prove that the equilateral triangle described on the hypotenuse of a right-angled triangle is equal to the sum of the equilateral triangles described on the sides containing the right angle.

[Let ABC be the triangle right-angled at C, and let BXC, CYA, AZB be the equilateral triangles. Draw CD perpendicular to AB, and join DZ. Then shew by Prop 15 that the $\triangle AYC =$ the $\triangle DAZ$, and similarly that the $\triangle BXC =$ the $\triangle BDZ$]

PROPOSITION 16 THEOREM

If four straight lines are proportional, the rectangle contained by the extremes is equal to the rectangle contained by the means

Conversely, if the rectangle contained by the extremes is equal to the rectangle contained by the means, the four straight lines are proportional

Let the st lines AB, CD, EF, GH be proportional, so that
 $AB \quad CD \quad EF \quad GH$

Then shall the rect $AB, GH =$ the rect CD, EF

From A draw AK perp to AB , and equal to GH 11, 3

From C draw CL perp to CD , and equal to EF

Complete the par^m KB, LD

Then because $AB \quad CD \quad EF \quad GH$,

and $EF = CL$, and $GH = AK$,

$AB \quad CD \quad CL \quad AK$,

Hyp
Constr

that is, the sides about equal angles of par^m KB, LD are reciprocally proportional,

$KB = LD$

VI 14

But KB is the rect AB, GH , for $AK = GH$, *Constr*

and LD is the rect CD, EF , for $CL = EF$,

the rect $AB, GH =$ the rect CD, EF

Conversely, let the rect $AB, GH =$ the rect CD, EF

then shall $AB \quad CD \quad EF \quad GH$

For, with the same construction as before,

because the rect $AB, GH =$ the rect CD, EF ,

and the rect $AB, GH = KB$, for $GH = AK$,

and the rect $CD, EF = LD$, for $EF = CL$,

$KB = LD$,

Hyp
Constr.

that is, the par^m KB, LD, which have the angle at A equal to the angle at C, are equal in area;

∴ the sides about the equal angles are reciprocally proportional:

that is, $AB : CD :: CL : AK,$

∴ $AB \cdot CD = CL \cdot AK$

Q. E. D.

PROPOSITION 17. THEOREM.

If three straight lines are proportional the rectangle contained by the extremes is equal to the square on the mean.

Conversely, if the rectangle contained by the extremes is equal to the square on the mean, the three straight lines are proportional.

Let the three st lines A, B, C be proportional, so that

$$A : B :: B : C.$$

Then shall the rect. A, C be equal to the sq. on B.

Take D equal to B

Then because $A : B :: B : C$, and $D = B$,

$$\therefore A \cdot B :: D \cdot C;$$

∴ the rect. A, C = the rect B, D, VI. 16.

but the rect. B, D = the sq on B, for $D = B$;

∴ the rect A, C = the sq on B

Conversely, let the rect A, C = the sq. on B.

then shall $A : B :: B : C$.

For, with the same construction as before,

because the rect. A, C = the sq. on B,

and the sq on B = the rect. B, D, for $D = B$;

∴ the rect A, C = the rect B, D,

$$A \cdot B :: D \cdot C,$$

that is, $A : B :: B : C$.

Hyp.

VI 16

Q. E. D.

EXERCISES

ON PROPOSITIONS 16 AND 17

1 Apply Proposition 16 to prove that if two chords of a circle intersect, the rectangle contained by the segments of the one is equal to the rectangle contained by the segments of the other

2 Prove that the rectangle contained by the sides of a right-angled triangle is equal to the rectangle contained by the hypotenuse and the perpendicular on it from the right angle

3 On a given straight line construct a rectangle equal to a given rectangle

4 ABCD is a parallelogram, from B any straight line is drawn cutting the diagonal AC at F, the side DC at G, and the side AD produced at E shew that the rectangle EF, FG is equal to the square on BF

5 On a given straight line as base describe an isosceles triangle equal to a given triangle

6 AB is a diameter of a circle, and any line ACD cuts the circle in C and the tangent at B in D, shew by Prop 17 that the rectangle AC, AD is constant

7 The exterior angle A of a triangle ABC is bisected by a straight line which meets the base in D and the circumscribed circle in E shew that the rectangle BA, AC is equal to the rectangle EA, AD

8 If two chords AB, AC drawn from any point A in the circumference of the circle ABC be produced to meet the tangent at the other extremity of the diameter through A in D and E, shew that the triangle AED is similar to the triangle ABC

9 At the extremities of a diameter of a circle tangents are drawn, these meet the tangent at a point P in Q and R shew that the rectangle QP, PR is constant for all positions of P

10 A is the vertex of an isosceles triangle ABC inscribed in a circle, and ADE is a straight line which cuts the base in D and the circle in E, shew that the rectangle EA, AD is equal to the square on AB

11 Two circles touch one another externally in A, a straight line touches the circles at B and C, and is produced to meet the straight line joining their centres at S shew that the rectangle SB, SC is equal to the square on SA

12 Divide a triangle into two equal parts by a straight line at right angles to one of the sides

DEFINITION. Two similar rectilineal figures are said to be **similarly situated** with respect to two of their sides when these sides are homologous [Book VI Def 5.]

PROPOSITION 18 PROBLEM

On a given straight line to describe a rectilineal figure similar and similarly situated to a given rectilineal figure

Let AB be the given st line, and CDEF the given rectil figure first suppose CDEF to be a quadrilateral.

It is required to describe on the st line AB, a rectil figure similar and similarly situated to CDEF.

Join DF

At A in BA make the $\angle BAG$ equal to the $\angle DCF$, I. 23
and at B in AB make the $\angle ABG$ equal to the $\angle CDF$,
the remaining $\angle AGB =$ the remaining $\angle CFD$, I. 32
and the $\triangle AGB$ is equiangular to the $\triangle CFD$

Again at B in GB make the $\angle GBH$ equal to the $\angle FDE$,
and at G in BG make the $\angle BGH$ equal to the $\angle DFE$; I. 23
 \therefore the remaining $\angle BHG =$ the remaining $\angle DEF$, I. 32.
and the $\triangle BHG$ is equiangular to the $\triangle DEF$
Then shall ABHG be the required figure

(1) To prove that the quadrilaterals are equiangular

Because the $\angle AGB =$ the $\angle CFD$,

and the $\angle BGH =$ the $\angle DFE$,

\therefore the whole $\angle AGH =$ the whole $\angle CFE$ *Constr* *Ax. 2.*

Similarly the $\angle ABH =$ the $\angle CDE$;

and the angles at A and H are respectively equal to the angles at C and E;

\therefore the fig ABHG is equiangular to the fig CDEF. *Constr.*

(11) To prove that the quadrilaterals have the sides about their equal angles proportional

Because the Δ^s BAG, DCF are equiangular,

$$AG : GB :: CF : FD \quad \text{VI 4}$$

And because the Δ^s BGH, DFE are equiangular,

$$\therefore BG : GH :: DF : FE, \\ \text{or equal, } AG : GH :: CF : FE \quad \text{V 14}$$

Similarly it may be shewn that

$$AB : BH :: CD : DE \\ \text{Also } BA : AG :: DC : CF, \quad \text{VI 4} \\ \text{and } GH : HB :: FE : ED,$$

the figs ABHG, CDEF have their sides about the equal angles proportional,

\therefore ABHG is similar to CDEF *Def 2*

In like manner the process of construction may be extended to a figure of five or more sides

Q.E.F

DEFINITION. When three magnitudes are proportionals the first is said to have to the third the **duplicate ratio** of that which it has to the second [Book v Def 13]

✓ PROPOSITION 19 THEOREM

Similar triangles are to one another in the duplicate ratio of their homologous sides

Let $\triangle ABC$, $\triangle DEF$ be similar triangles, having the $\angle ABC$ equal to the $\angle DEF$, and let BC and EF be homologous sides then shall the $\triangle ABC$ be to the $\triangle DEF$ in the duplicate ratio of BC to EF .

To BC and EF take a third proportional BG ,
so that $BC : EF :: EF : BG$ VI 11
Join AG

Then because the $\triangle^s ABC$, DEF are similar, *Hyp*

$\therefore AB : BC :: DE : EF$,
, *alternately*, $AB : DE :: BC : EF$, v 11.
but $BC : EF :: EF : BG$, *Constr.*
 $\therefore AB : DE :: EF : BG$, v 1

that is, the sides of the $\triangle^s ABG$, DEF about the equal angles at B and E are reciprocally proportional,
the $\triangle ABG =$ the $\triangle DEF$ VI 15

Again, because $BC : EF :: EF : BG$, *Constr*

$\therefore BC : BG$ in the duplicate ratio of BC to EF . *Def*

But the $\triangle ABC$ the $\triangle ABG :: BC : BG$, VI 1
the $\triangle ABC$ the $\triangle ABG$ in the duplicate ratio of BC to EF v 1

and the $\triangle ABG =$ the $\triangle DEF$, *Proved*

\therefore the $\triangle ABC$ the $\triangle DEF$ in the duplicate ratio of BC to EF Q E D

PROPOSITION 20 THEOREM

Similar polygons may be divided into the same number of similar triangles, having the same ratio each to each that the polygons have, and the polygons are to one another in the duplicate ratio of their homologous sides

Let $ABCDE$, $FGHLK$ be similar polygons, and let AB be the side homologous to FG ,
then (i) the polygons may be divided into the same number of similar triangles,

(ii) these triangles shall have each to each the same ratio that the polygons have,

(iii) the polygon $ABCDE$ shall be to the polygon $FGHLK$ in the duplicate ratio of AB to FG

Join EB , EC , LG , LH .

(i) Then because the polygon $ABCDE$ is similar to the polygon $FGHLK$,

the $\angle EAB =$ the $\angle LFG$,

and $EA : AB :: LF : FG$, VI Def 2

the $\triangle EAB$ is similar to the $\triangle LFG$; VI 6

\therefore the $\angle ABE =$ the $\angle FGL$

But, because the polygons are similar, Hyp

the $\angle ABC =$ the $\angle FGH$, VI Def 2

the remaining $\angle ECB =$ the remaining $\angle LGH$

And because the $\triangle^s ABE$, FGL are similar, Proved

$EB : BA :: LG : GF$,

and because the polygons are similar, Hyp

$AB : BC :: FG : GH$, VI Def 2

\therefore , *ex aequali*, $EB : BC :: LG : GH$, V 14

that is, the sides about the equal $\angle^s EBC$, LGH are proportionals,

the $\triangle EBC$ is similar to the $\triangle LGH$ VI 6

In the same way it may be proved that the $\triangle ECD$ is similar to the $\triangle LHK$.

the polygons have been divided into the same number of similar triangles

(ii) Again, because the $\triangle ABE$ is similar to the $\triangle FGL$,
the $\triangle ABE$ is to the $\triangle FGL$ in the duplicate ratio
of $EB : LG$, VI. 19

and, in like manner,

the $\triangle EBC$ is to the $\triangle LGH$ in the duplicate ratio
of EB to LG ,

the $\triangle ABE \cdot$ the $\triangle FGL \cdot$ the $\triangle EBC$; the $\triangle LGH$ v. 1

In like manner it can be shewn that

the $\triangle EBC \cdot$ the $\triangle LGH \cdot$ the $\triangle EDC$: the $\triangle LKH$.

the $\triangle ABE$ the $\triangle FGL$ the $\triangle EBC$: the $\triangle LGH$

the $\triangle EDC$. the $\triangle LKH$

But when any number of ratios are equal, as each antecedent is to its consequent so is the sum of all the antecedents to the sum of all the consequents, v 12

the $\triangle ABE \cdot$ the $\triangle LFG$ the fig $ABCDE$: the fig $FGHKL$.

(iii) Now the $\triangle EAB$: the $\triangle LFG$ in the duplicate ratio
of $AB : FG$,

and the $\triangle EAB$ the $\triangle LFG$. the fig $ABCDE$ the fig $FGHKL$;

the fig $ABCDE$ the fig $FGHKL$ in the duplicate ratio
of $AB : FG$ Q E D.

COROLLARY 1 Let a third proportional X be taken
to AB and FG ,

then AB is to X in the duplicate ratio of $AB : FG$;

but the fig $ABCDE$: the fig $FGHKL$ in the duplicate
ratio of $AB : FG$.

Hence, *if three straight lines are proportionals, as the first is to the third, so is any rectilineal figure described on the first to a similar and similarly described rectilineal figure on the second*

COROLLARY 2. It follows that *similar rectilineal figures are to one another as the squares on their homologous sides.* For squares are similar figures and therefore are to one another in the duplicate ratio of their sides

PROPOSITION 21 THEOREM

Rectilineal figures which are similar to the same rectilineal figure, are also similar to each other

Let each of the rectilineal figures A and B be similar to C
then shall A be similar to B

For because A is similar to C, *Hyp*
A is equiangular to C, and the sides about their equal
angles are proportionals vi Def 2

Again, because B is similar to C, *Hyp*
B is equiangular to C, and the sides about their equal
angles are proportionals vi Def 2
A and B are each of them equiangular to C, and have
the sides about the equal angles proportional to the cor-
responding sides of C,

A is equiangular to B, and the sides about their equal
angles are proportionals, v 1.

A is similar to B

Q E D

PROPOSITION 22 THEOREM

If four straight lines be proportional and a pair of similar rectilineal figures be similarly described on the first and second, and also a pair on the third and fourth, these figures shall be proportional

Conversely, if a rectilineal figure on the first of four straight lines be to the similar and similarly described figure on the second as a rectilineal figure on the third is to the similar and similarly described figure on the fourth, the four straight lines shall be proportional.

Let AB, CD, EF, GH be proportionals,
so that $AB : CD = EF : GH$,
and let similar figures KAB, LCD be similarly described on
AB, CD, and also let similar figs MF, NH be similarly
described on EF, GH.
then shall

the fig KAB the fig LCD : the fig MF the fig NH

To AB and CD take a third proportional X, -VI 11.
and to EF and GH take a third proportional O,

then $AB : CD = CD : X$, Constr
and $EF : GH = GH : O$.

But $AB : CD = EF : GH$, Hyp
 $CD : X = GH : O$, v 1

, *ex æquali*, $AB : X = EF : O$ v. 14

But $AB : X$ the fig KAB : the fig LCD, VI. 20, Cor

and $EF : O$ the fig MF the fig NH,

the fig KAB the fig LCD : the fig MF the fig NH
v 1.

Conversely,

let the fig KAB the fig LCD the fig MF the fig NH,
then shall AB CD EF GH

To AB, CD, and EF take a fourth proportional PR VI 12
and on PR describe the fig SR similar and similarly situated
to either of the figs MF, NH VI 18

Then because AB CD EF PR, *Constr*

, by the former part of the proposition,
the fig KAB the fig LCD the fig MF the fig SR

But

the fig KAB the fig LCD the fig MF the fig NH *Hyp*

the fig MF the fig SR the fig MF the fig NH, v 1

the fig SR = the fig NH

And since the figs SR and NH are similar and similarly
situated,

$$PR = GH^*$$

Now AB CD EF PR,
AB CD EF GH

Constr

Q E D

* Euclid here assumes that if two similar and similarly situated figures are equal, their homologous sides are equal. The proof is easy and may be left as an exercise for the student.

DEFINITION When there are any number of magnitudes of the same kind, the first is said to have to the last the ratio compounded of the ratios of the first to the second, of the second to the third, and so on up to the ratio of the last but one to the last magnitude [Book v Def 12]

↓ PROPOSITION 23 THEOREM

Parallelograms which are equiangular to one another have to one another the ratio which is compounded of the ratios of their sides

Let the par^m AC be equiangular to the par^m CF, having the $\angle BCD$ equal to the $\angle ECG$

then shall the par^m AC have to the par^m CF the ratio compounded of the ratios BC CG and DC CE.

Let the par^ms be placed so that BC and CG are in a st line,
then DC and CE are also in a st line I 14

Complete the par^m DG.

Take any st line K,

and to BC, CG, and K find a fourth proportional L, VI. 12.

and to DC, CE, and L take a fourth proportional M,

then BC CG K L,

and DC CE L M

But K M is the ratio compounded of the ratios

K L and L M, v Def 12

that is, K M is the ratio compounded of the ratios

BC CG and DC CE

Now the par^m AC the par^m CH BC CG VI 1

K L, Constr

and the par^m CH the par^m CF \therefore DC CE VI 1

L M, Constr.

\therefore , ex æquali, the par^m AC the par^m CF \cdot K \cdot M v 14

But K M is the ratio compounded of the ratios of the sides;

\therefore the par^m AC has to the par^m CF the ratio compounded
of the ratios of the sides Q E D

EXERCISE

The areas of two triangles or parallelograms are to one another in the ratio compounded of the ratios of their bases and of their altitudes

PROPOSITION 24 THEOREM

Parallelograms about a diagonal of any parallelogram are similar to the whole parallelogram and to one another

Let $ABCD$ be a par^m of which AC is a diagonal,
 and let EG, HK be par^m s about AC
 then shall the par^m s EG, HK be similar to the par^m $ABCD$,
 and to one another

For, because DC is par^l to GF ,
 the $\angle ADC = \text{the } \angle AGF$, I 29

and because BC is par^l to EF ,
 the $\angle ABC = \text{the } \angle AEF$, I 29

and each of the \angle^s BCD, EFG is equal to the opp \angle BAD ,
 the $\angle BCD = \text{the } \angle EFG$, [I 34

the par^m $ABCD$ is equiangular to the par^m $AEFG$

Again in the \triangle^s BAC, EAF ,
 because the $\angle ABC = \text{the } \angle AEF$, I 29
 and the $\angle BAC$ is common,

\triangle^s BAC, EAF are equiangular to one another, I 32

$AB \quad BC \quad AE \quad EF$ VI 4

But $BC = AD$, and $EF = AG$, I 34

$AB \quad AD \quad AE \quad AG$,

and $DC \quad CB \quad GF \quad FE$,

and $CD \quad DA \quad FG \quad GA$,

the sides of the par^m s $ABCD, AEFG$ about their equal
 angles are proportional,

the par^m $ABCD$ is similar to the par^m $AEFG$ VI Def 2

In the same way it may be proved that the par^m $ABCD$
 is similar to the par^m $FKCH$,

each of the par^m s EG, HK is similar to the whole par^m ,
 the par^m EG is similar to the par^m HK VI 21.

PROPOSITION 25. PROBLEM.

To describe a rectilineal figure which shall be equal to one and similar to another rectilineal figure

Let E and S be two rectilineal figures.
it is required to describe a figure equal to the fig. E and similar to the fig. S.

On AB a side of the fig. S describe a par^m ABCD equal to S, and on BC describe a par^m CBGF equal to the fig. E, and having the $\angle CBG$ equal to the $\angle DAB$. I. 15.

then AB and BG are in one st line, and also DC and CF in one st line

Between AB and BG find a mean proportional HK, VI 13 and on HK describe the fig P, similar and similarly situated to the fig. S. VI 18.

then P shall be the figure required

Because AB : HK \therefore HK : BG, Constr.

AB \cdot BG \therefore the fig S the fig P VI 20, Cor

But AB \cdot BG \therefore the par^m AC the par^m BF,

\therefore the fig. S \therefore the fig P \therefore the par^m AC the par^m BF; V. 1

and the fig S = the par^m AC; Constr

\therefore the fig P = the par^m BF

= the fig E Constr

And since, by construction, the fig P is similar to the fig. S,
 \therefore P is the rectil figure required

Q E F.

PROPOSITION 26 THEOREM

If two similar parallelograms have a common angle, and be similarly situated, they are about the same diagonal

Let the par^{ms} ABCD, AEFG be similar and similarly situated, and have the common angle BAD

then shall these par^{ms} be about the same diagonal

Join AC

Then if AC does not pass through F, let it cut FG, or FG produced, at H

Join AF,

and through H draw HK par^l to AD or BC 1 31

Then the par^{ms} BD and KG are similar, since they are about the same diagonal AHC, VI 24

DA AB GA AK

But because the par^{ms} BD and EG are similar, *Hyp*

DA AB GA AE, VI Def 2

GA · AK GA AE,

AK = AE, which is impossible,

AC must pass through F,

that is, the par^{ms} BD, EG are about the same diagonal

Q E D

Obs Propositions 27, 28, 29 being cumbrous in form and of little value as geometrical results are now very generally omitted

DEFINITION. A straight line is said to be divided in extreme and mean ratio, when the whole is to the greater segment as the greater segment is to the less

[Book VI Def. 4.]

PROPOSITION 30 PROBLEM

To divide a given straight line in extreme and mean ratio.

Let AB be the given st line:

it is required to divide it in extreme and mean ratio

Divide AB in C so that the rect. AB, BC may be equal to the sq. on AC

II. 11

Then because the rect. AB, BC = the sq. on AC,

$$AB \cdot AC = AC \cdot BC$$

VI. 17

Q E F.

EXERCISES

1 ABCDE is a regular pentagon, if the lines BE and AD intersect in O, shew that each of them is divided in extreme and mean ratio.

2 If the radius of a circle is cut in extreme and mean ratio, the greater segment is equal to the side of a regular decagon inscribed in the circle

✓ PROPOSITION 31 THEOREM

In a right-angled triangle, any rectilineal figure described on the hypotenuse is equal to the sum of the two similar and similarly described figures on the sides containing the right angle

Let ABC be a right-angled triangle of which BC is the hypotenuse, and let P, Q, R be similar and similarly described figures on BC, CA, AB respectively
then shall the fig P be equal to the sum of the figs Q and R

Draw AD perp to BC

Then the Δ^s CBA, ABD are similar, VI 8

CB BA BA BD,

CB BD the fig P the fig R, VI 20, Cor

, *inversely*, BD BC the fig R the fig P V 2

In like manner DC BC the fig Q the fig P, -

the sum of BD, DC BC the sum of figs R, Q fig P, V 15

but BC = the sum of BD, DC,

the fig P = the sum of the figs R and Q

Q.E.D.

NOTE This proposition is a generalization of the 47th Prop of Book I. It will be a useful exercise for the student to deduce the general theorem from the particular case with the aid of Prop 20, Cor 2

EXERCISES

1. In a right angled triangle if a perpendicular be drawn from the right angle to the opposite side, the segments of the hypotenuse are in the duplicate ratio of the sides containing the right angle.

2. If, in Proposition 31, the figure on the hypotenuse is equal to the given triangle, the figures on the other two sides are each equal to one of the parts into which the triangle is divided by the perpendicular from the right angle to the hypotenuse

3. AX and BY are medians of the triangle ABC which meet in G. if XY be joined, compare the areas of the triangles AGB, XGY.

4. Shew that similar triangles are to one another in the duplicate ratio of (i) corresponding medians, (ii) the radii of their inscribed circles, (iii) the radii of their circumscribed circles.

5. DEF is the pedal triangle of the triangle ABC, prove that the triangle ABC is to the triangle DBF in the duplicate ratio of AB to BD. Hence shew that

$$\text{the fig AFDC : the } \triangle BFD :: AD^2 : BD^2$$

6. The base BC of a triangle ABC is produced to a point D such that $BD : DC$ in the duplicate ratio of $BA : AC$. Shew that AD is a mean proportional between BD and DC

7. Bisect a triangle by a line drawn parallel to one of its sides

8. Shew how to draw a line parallel to the base of a triangle so as to form with the other two sides produced a triangle double of the given triangle.

9. If through any point within a triangle lines be drawn from the angles to cut the opposite sides, the segments of any one side will have to each other the ratio compounded of the ratios of the segments of the other sides

10. Draw a straight line parallel to the base of an isosceles triangle so as to cut off a triangle which has to the whole triangle the ratio of the base to a side

11. Through a given point, between two straight lines containing a given angle, draw a line which shall cut off a triangle equal to a given rectilineal figure

Obs The 32nd Proposition as given by Euclid is defective, and as it is never applied, we have omitted it

PROPOSITION 33 THEOREM

In equal circles, angles, whether at the centres or the circumferences, have the same ratio as the arcs on which they stand. so also have the sectors

Let ABC and DEF be equal circles, and let BGC, EHF be angles at the centres, and BAC and EDF angles at the \odot^{cs} , then shall

- (i) the \angle BGC the \angle EHF the arc BC the arc EF,
- (ii) the \angle BAC the \angle EDF the arc BC the arc EF,
- (iii) the sector BGC the sector EHF the arc BC the arc EF

Along the \odot^{ce} of the \odot ABC take any number of arcs CK, KL each equal to BC, and along the \odot^{ce} of the \odot DEF take any number of arcs FM, MN, NR each equal to EF

Join GK, GL, HM, HN, HR

- (i) Then the \angle BGC, CGK, KGL are all equal,
for they stand on the equal arcs BC, CK, KL III 27
the \angle BGL is the same multiple of the \angle BGC that the arc BL is of the arc BC

Similarly the \angle EHR is the same multiple of the \angle EHF that the arc ER is of the arc EF.

And if the arc BL = the arc ER,

the \angle BGL = the \angle EHR, III 27

and if the arc BL is greater than the arc ER,

the \angle BGL is greater than the \angle EHR,

and if the arc BL is less than the arc ER,

the \angle BGL is less than the \angle EHR.

Now since there are four magnitudes, namely the \angle^s BGC, EHF and the arcs BC, EF; and of the antecedents any equimultiples have been taken, namely the \angle BGL and the arc BL, and of the consequents any equimultiples have been taken, namely the \angle EHR and the arc ER and it has been proved that the \angle BGL is greater than, equal to, or less than the \angle EHR according as BL is greater than, equal to, or less than ER,

∴ the four magnitudes are proportionals, v. Def 4.
that is, the \angle BGC the \angle EHF the arc BC : the arc EF.

(ii) And since the \angle BGC = twice the \angle BAC, III. 20.

and the \angle EHF = twice the \angle EDF

∴ the \angle BAC the \angle EDF the arc BC the arc EF. v 8

(iii) Join BC, CK, and in the arcs BC, CK take any points X, O.

Join BX, XC, CO, OK.

Then in the \triangle^s BGC, CGK,

Because $\left\{ \begin{array}{l} BG = CG, \\ GC = GK, \\ \text{and the } \angle BGC = \text{the } \angle CGK, \\ \therefore BC = CK, \\ \text{and the } \triangle BGC = \text{the } \triangle CGK. \end{array} \right. \quad \begin{array}{l} \text{III 27} \\ \text{I 4} \end{array}$

And because the arc BC = the arc CK, Constr

the remaining arc BAC = the remaining arc CAK.

∴ the \angle BXC = the \angle COK; III 27.

∴ the segment BXC is similar to the segment COK, III Def

and they stand on equal chords BC, CK,

the segment BXC = the segment COK. III. 24

And the \triangle BGC = the \triangle CGK;

the sector BGC = the sector CGK.

PROPOSITION B. THEOREM

If the vertical angle of a triangle be bisected by a straight line which cuts the base, the rectangle contained by the sides of the triangle shall be equal to the rectangle contained by the segments of the base, together with the square on the straight line which bisects the angle

Let ABC be a triangle having the \angle BAC bisected by AD; then shall

the rect BA, AC = the rect BD, DC, with the sq on AD

Describe a circle about the \triangle ABC, IV 5
and produce AD to meet the \bigcirc^{ce} in E
Join EC.

Then in the \triangle^s BAD, EAC,
because the \angle BAD = the \angle EAC, Hyp
and the \angle ABD = the \angle AEC in the same segment, III 21.
 \therefore the \triangle BAD is equiangular to the \triangle EAC. I 32

\therefore BA AD = EA AC; VI 4.
the rect BA, AC = the rect EA, AD, VI 16
= the rect ED, DA, with the sq on AD II 3

But the rect ED, DA = the rect BD, DC, III. 35
the rect BA, AC = the rect BD, DC, with the sq on AD Q E D

EXERCISE

If the vertical angle BAC be externally bisected by a straight line which meets the base in D, shew that the rectangle contained by BA, AC together with the square on AD is equal to the rectangle contained by the segments of the base

PROPOSITION C THEOREM

If from the vertical angle of a triangle a straight line be drawn perpendicular to the base, the rectangle contained by the sides of the triangle shall be equal to the rectangle contained by the perpendicular and the diameter of the circle described about the triangle

Let ABC be a triangle, and let AD be the perp from A to BC
 then the rect BA, AC shall be equal to the rect contained by AD and the diameter of the circle circumscribed about the $\triangle ABC$.

Describe a circle about the $\triangle ABC$,
 draw the diameter AE , and join EC iv. 5.

Then in the $\triangle BAD, EAC$,
 the rt angle $BDA =$ the rt angle ACE , in the semicircle ACE ,
 and the $\angle ABD =$ the $\angle AEC$, in the same segment, iii 21
 the $\triangle BAD$ is equiangular to the $\triangle EAC$, i 32
 $BA \ AD \ EA \ AC$, vi 4
 the rect $BA, AC =$ the rect. EA, AD vi 16
q. e. d.

PROPOSITION D. THEOREM

The rectangle contained by the diagonals of a quadrilateral inscribed in a circle is equal to the sum of the two rectangles contained by its opposite sides

Let ABCD be a quadrilateral inscribed in a circle, and let AC, BD be its diagonals
then the rect AC, BD shall be equal to the sum of the rectangles AB, CD and BC, AD

Make the $\angle DAE$ equal to the $\angle BAC$, I 23
to each add the $\angle EAC$,
then the $\angle DAC =$ the $\angle BAE$

Then in the \triangle^s EAB, DAC,
the $\angle EAB =$ the $\angle DAC$,

and the $\angle ABE =$ the $\angle ACD$ in the same segment, III 21

the triangles are equiangular to one another, I 32

$AB \cdot BE \cdot AC \cdot CD$, VI 4

the rect AB, CD = the rect AC, EB VI 16

Again in the \triangle^s DAE, CAB,

the $\angle DAE =$ the $\angle CAB$, Consts

and the $\angle ADE =$ the $\angle ACB$, in the same segment, III 21

the triangles are equiangular to one another, I 32

$AD \cdot DE \cdot AC \cdot CB$, VI 4.

the rect BC, AD = the rect AC, DE VI 16

But the rect AB, CD = the rect AC, EB Proved

the sum of the rects BC, AD and AB, CD = the sum of
the rects AC, DE and AC, EB,

that is, the sum of the rects BC, AD and AB, CD

= the rect AC, BD II 1

Q E D

NOTE Propositions B, C, and D do not occur in Euclid, but were added by Robert Simson

Prop D is usually known as Ptolemy's theorem, and it is the particular case of the following more general theorem

The rectangle contained by the diagonals of a quadrilateral is less than the sum of the rectangles contained by its opposite sides, unless a circle can be circumscribed about the quadrilateral, in which case it is equal to that sum

EXERCISES

1 ABC is an isosceles triangle, and on the base, or base produced, any point X is taken shew that the circumscribed circles of the triangles ABX, ACX are equal

2 From the extremities B, C of the base of an isosceles triangle ABC, straight lines are drawn perpendicular to AB, AC respectively, and intersecting at D shew that the rectangle BC, AD is double of the rectangle AB, DB

3 If the diagonals of a quadrilateral inscribed in a circle are at right angles, the sum of the rectangles of the opposite sides is double the area of the figure

4 ABCD is a quadrilateral inscribed in a circle, and the diagonal BD bisects AC shew that the rectangle AD, AB is equal to the rectangle DC, CB

5 If the vertex A of a triangle ABC be joined to any point in the base, it will divide the triangle into two triangles such that their circumscribed circles have radii in the ratio of AB to AC

6 Construct a triangle, having given the base, the vertical angle, and the rectangle contained by the sides

7 Two triangles of equal area are inscribed in the same circle shew that the rectangle contained by any two sides of the one is to the rectangle contained by any two sides of the other as the base of the second is to the base of the first

8 A circle is described round an equilateral triangle, and from any point in the circumference straight lines are drawn to the angular points of the triangle shew that one of these straight lines is equal to the sum of the other two

9 ABCD is a quadrilateral inscribed in a circle, and BD bisects the angle ABC if the points A and C are fixed on the circumference of the circle and B is variable in position, shew that the sum of AB and BC has a constant ratio to BD

THEOREMS AND EXAMPLES ON BOOK VI

I ON HARMONIC SECTION

1 To divide a given straight line internally and externally so that its segments may be in a given ratio

Let AB be the given st line, and L, M two other st lines which determine the given ratio it is required to divide AB internally and externally in the ratio L M

Through A and B draw any two par^l st lines AH, BK

From AH cut off Aa equal to L,

and from BK cut off Bb and Bb' each equal to M, Bb' being taken in the same direction as Aa, and Bb in the opposite direction

Join ab, cutting AB in P;

join ab', and produce it to cut AB externally at Q

Then AB is divided internally at P and externally at Q,
so that $\frac{AP}{AQ} = \frac{PB}{QB} = \frac{L}{M}$,
and

The proof follows at once from Euclid vi 4

Obs The solution is *singular*, that is, only one internal and one external point can be found that will divide the given straight line into segments which have the given ratio

DEFINITION

- (A finite straight line is said to be cut harmonically when it is divided internally and externally into segments which have the same ratio

Thus AB is divided harmonically at P and Q, if

$$AP \cdot PB = AQ \cdot QB$$

P and Q are said to be harmonic conjugates of A and B

If P and Q divide AB internally and externally in the same ratio, it is easy to show that A and B divide PQ internally and externally in the same ratio hence A and B are harmonic conjugates of P and Q

Example The base of a triangle is divided harmonically by the internal and external bisectors of the vertical angle for in each case the segments of the base are in the ratio of the other sides of the triangle [Euclid vi 3 and A]

Obs We shall use the terms *Arithmetic*, *Geometric*, and *Harmonic Means* in their ordinary Algebraical sense

- 1 If AB is divided internally at P and externally at Q in the same ratio, then AB is the harmonic mean between AQ and AP

For by hypothesis $AQ \cdot QB = AP \cdot PB$,
 , alternately, $AQ \cdot AP = QB \cdot PB$,
 that is, $AQ \cdot AP = AQ \cdot AB - AB \cdot AP$,
 which proves the proposition

- 2 If AB is divided harmonically at P and Q, and O is the middle point of AB,

then shall $OP \cdot OQ = OA^2$

For since AB is divided harmonically at P and Q,

$$\begin{aligned} AP \cdot PB &= AQ \cdot QB, \\ AP - PB \cdot AP + PB &= AQ - QB \cdot AQ + QB, \\ \text{or, } 2OP \cdot 2OA &= 2OA \cdot 2OQ, \\ OP \cdot OQ &= OA^2 \end{aligned}$$

Conversely, if it may be shewn that

$$OP \cdot OQ = OA^2,$$

that is, that $AP \cdot PB = AQ \cdot QB$,
 that is, that AB is divided harmonically at P and Q

3 The Arithmetic, Geometric and Harmonic means of two straight lines may be thus represented graphically

In the adjoining figure, two tangents AH, AK are drawn from any external point A to the circle PHQK, HK is the chord of contact, and the st line joining A to the centre O cuts the \odot^e at P and Q

Then (i) AO is the Arithmetic mean between AP and AQ for clearly
 $AO = \frac{1}{2}(AP + AQ)$

(ii) AH is the Geometric mean between AP and AQ
 for $AH^2 = AP \cdot AQ$ III 36

(iii) AB is the Harmonic mean between AP and AQ
 for $OA \cdot OB = OP^2$ Ex 1, p 233

AB is cut harmonically at P and Q Ex 1, p 360

That is, AB is the Harmonic mean between AP and AQ

And from the similar triangles OAH, HAB,

$$\begin{aligned} OA : AH &= AH : AB, \\ AO : AB &= AH^2; \end{aligned}$$

VI. 17

the Geometric mean between two straight lines is the mean proportional between their Arithmetic and Harmonic means

4 Given the base of a triangle and the ratio of the other sides, to find the locus of the vertex

Let BC be the given base, and let BAC be any triangle standing upon it, such that $BA : AC =$ the given ratio

it is required to find the locus of A

Bisect the $\angle BAC$ internally and externally by AP, AQ

Then BC is divided internally at P, and externally at Q, so that $BP : PC = BQ : QC =$ the given ratio, P and Q are fixed points

And since AP, AQ are the internal and external bisectors of the $\angle BAC$,

the $\angle PAQ$ is a rt angle,
 the locus of A is a circle described on PQ as diameter

EXERCISE Given three points B, P, C in a straight line find the locus of points at which BP and PC subtend equal angles

DEFINITIONS

1 A series of points in a straight line is called a **range**. If the range consists of four points, of which one pair are harmonic conjugates with respect to the other pair, it is said to be a **harmonic range**.

2 A series of straight lines drawn through a point is called a **pencil**

The point of concurrence is called the **vertex** of the pencil, and each of the straight lines is called a **ray**

A pencil of four rays drawn from any point to a harmonic range is said to be a **harmonic pencil**.

3 A straight line drawn to cut a system of lines is called a **transversal**

4 A system of four straight lines, no three of which are concurrent, is called a **complete quadrilateral**

These straight lines will intersect two and two in six points, called the **vertices** of the quadrilateral, the three straight lines which join opposite vertices are **diagonals**

THEOREMS ON HARMONIC SECTION

1 If a transversal is drawn parallel to one ray of a harmonic pencil, the other three rays intercept equal parts upon it and conversely

2 Any transversal is cut harmonically by the rays of a harmonic pencil

3 In a harmonic pencil, if one ray bisect the angle between the other pair of rays, it is perpendicular to its conjugate ray. Conversely if one pair of rays form a right angle, then they bisect internally and externally the angle between the other pair

4 If A, B, C, D and a, b, c, d are harmonic ranges, one on each of two given straight lines, and if Aa, Bb, Cc , the straight lines which join three pairs of corresponding points, meet at S , then will Dd also pass through S

5 If two straight lines intersect at O , and if O, C, B, D and O, c, b, d are two harmonic ranges one on each straight line (the points corresponding as indicated by the letters), then Cc, Bb, Dd will be concurrent also Cd, Bb, Dc will be concurrent

6 Use Theorem 5 to prove that in a complete quadrilateral in which the three diagonals are drawn, the straight line joining any pair of opposite vertices is cut harmonically by the other two diagonals.

II ON CENTRES OF SIMILARITY AND SIMILITUDE.

1 If any two unequal similar figures are placed so that their homologous sides are parallel, the lines joining corresponding points in the two figures meet in a point, whose distances from any two corresponding points are in the ratio of any pair of homologous sides.

Let $ABCD$, $A'B'C'D'$ be two similar figures, and let them be placed so that their homologous sides are parallel, namely, AB , BC , CD , DA parallel to $A'B'$, $B'C'$, $C'D'$, $D'A'$ respectively. then shall AA' , BB' , CC' , DD' meet in a point, whose distances from any two corresponding points shall be in the ratio of any pair of homologous sides

Let AA' meet BB' , produced if necessary, in S

Then because AB is par^l to $A'B'$,
the Δ^s SAB , $SA'B'$ are equiangular,

Hyp

$$SA : SA' = AB : A'B',$$

VI 4

AA' divides BB' , externally or internally, in the ratio of AB to $A'B'$

Similarly it may be shewn that CC' divides BB' in the ratio of BC to $B'C'$

But since the figures are similar,

$$BC : B'C' = AB : A'B',$$

AA' and CC' divide BB' in the same ratio,

that is, AA' , BB' , CC' meet in the same point S

In like manner it may be proved that DD' meets CC' in the point S

AA' , BB' , CC' , DD' are concurrent, and each of these lines is divided at S in the ratio of a pair of homologous sides of the two figures

Q. E. D.

COR If any line is drawn through S meeting any pair of homologous sides in K and K' , the ratio $SK : SK'$ is constant, and equal to the ratio of any pair of homologous sides

NOTE It will be seen that the lines joining corresponding points are divided externally or internally at S according as the corresponding sides are drawn in the same or in opposite directions. In either case the point of concurrence S is called a centre of similarity of the two figures

2 A common tangent STT' to two circles whose centres are C, C' , meets the line of centres in S . If through S any straight line is drawn meeting these two circles in P, Q , and P', Q' , respectively, then the radii CP, CQ shall be respectively parallel to $C'P', C'Q'$. Also the rectangles $SQ \cdot SP', SP \cdot SQ'$ shall each be equal to the rectangle $ST \cdot ST'$.

Join CT, CP, CQ and $C'T', C'P', C'Q'$
Then since each of the $\angle^s CTS, C'T'S$ is a right angle, III 18.

CT is par^l to $C'T'$,
the $\Delta^s SCT, SC'T'$ are equiangular,

$$\frac{SC}{SC'} = \frac{CT}{C'T'} \\ = \frac{CP}{C'P'}$$

the $\Delta^s SCP, SC'P'$ are similar, VI 7
the $\angle SCP = \angle SC'P'$,

CP is par^l to $C'P'$

Similarly CQ is par^l to $C'Q'$

Again, it easily follows that TP, TQ are par^l to $T'P', T'Q'$ respectively,

the $\Delta^s STP, ST'P'$ are similar

Now the rect $SP \cdot SQ =$ the sq on ST , III 37

$$SP \cdot ST = ST \cdot SQ, \quad VI 16$$

and $SP \cdot ST = SP' \cdot ST'$,

$$ST \cdot SQ = SP' \cdot ST',$$

the rect $ST \cdot ST' = SQ \cdot SP'$

In the same way it may be proved that

$$\text{the rect } SP \cdot SQ' = \text{the rect } ST \cdot ST'$$

Q E D

Cor. 1 It has been proved that

$$\frac{SC}{SC'} = \frac{CP}{C'P'},$$

thus the external common tangents to the two circles meet at a point S which divides the line of centres externally in the ratio of the radii

Similarly it may be shown that the transverse common tangents meet at a point S' which divides the line of centres internally in the ratio of the radii

Cor. 2 CC' is divided harmonically at S and S'

DEFINITION The points S and S' which divide externally and internally the line of centres of two circles in the ratio of their radii are called the external and internal centres of similitude respectively

EXAMPLES

- 1 Inscribe a square in a given triangle
- 2 In a given triangle inscribe a triangle similar and similarly situated to a given triangle
- 3 Inscribe a square in a given sector of circle, so that two angular points shall be on the arc of the sector and the other two on the bounding radii
- 4 In the figure on page 278, if DI meets the inscribed circle in X , shew that A, X, D_1 are collinear. Also if AI_1 meets the base in Y shew that II_1 is divided harmonically at Y and A .
- 5 With the notation on page 282 shew that O and G are respectively the external and internal centres of similitude of the circumscribed and nine-points circle
- 6 If a variable circle touches two fixed circles, the line joining their points of contact passes through a centre of similitude. Distinguish between the different cases
- 7 Describe a circle which shall touch two given circles and pass through a given point
- 8 Describe a circle which shall touch three given circles
- 9 C_1, C_2, C_3 are the centres of three given circles, I_1, E_1 are the internal and external centres of similitude of the pair of circles whose centres are C_2, C_3 , and I_2, E_2, I_3, E_3 have similar meanings with regard to the other two pairs of circles. shew that
 - (i) I_1C_1, I_2C_2, I_3C_3 are concurrent,
 - (ii) the six points $I_1, I_2, I_3, E_1, E_2, E_3$ lie three and three on four straight lines

III ON POLE AND POLAR

DEFINITIONS

(1) If in any straight line drawn from the centre of a circle two points are taken such that the rectangle contained by their distances from the centre is equal to the square on the radius, each point is said to be the **inverse** of the other

Thus in the figure given below, if O is the centre of the circle, and if $OP \cdot OQ = (\text{radius})^2$, then each of the points P and Q is the inverse of the other

It is clear that if one of these points is within the circle the other must be without it

(11) The polar of a given point with respect to a given circle is the straight line drawn through the inverse of the given point at right angles to the line which joins the given point to the centre and with reference to the polar the given point is called the pole.

Thus in the adjoining figure, if $OP \cdot OQ = (\text{radius})^2$, and if through

P and Q, LM and HK are drawn perp to OP, then HK is the polar of the point P, and P is the pole of the line HK also LM is the polar of the point Q, and Q the pole of LM

It is clear that the polar of an external point must intersect the circle, and that the polar of an internal point must fall without it also that the polar of a point on the circumference is the tangent at that point

1 Now it has been proved [see Ex 1, page 233] that if from an external point P two tangents PH, PK are drawn to a circle, of which O is the centre, then OP cuts the chord of contact HK at right angles at Q,

so that $OP \cdot OQ = (\text{radius})^2$, HK is the polar of P with respect to the circle

Def 2

Hence we conclude that The Polar of an external point with reference to a circle is the chord of contact of tangents drawn from the given point to the circle

The following Theorem is known as the Reciprocal Property of Pole and Polar

2 If A and P are any two points, and if the polar of A with respect to any circle passes through P , then the polar of P must pass through A

Let BC be the polar of the point A with respect to a circle whose centre is O , and let BC pass through P then shall the polar of P pass through A

Join OP , and from A draw AQ perp to OP . We shall shew that AQ is the polar of P .

Now since BC is the polar of A ,

∴ the $\angle ABP$ is a rt angle,

Def 2, page 360

and the $\angle AQP$ is a rt angle. Constr.

∴ the four points A, B, P, Q are concyclic,

$$OQ \cdot OP = OA \cdot OB \quad \text{III. 36}$$

$$= (\text{radius})^2, \text{ for } CB \text{ is the polar of } A$$

P and Q are inverse points with respect to the given circle

And since AQ is perp to OP ,

AQ is the polar of P

That is, the polar of P passes through A

Q E D

A similar proof applies to the case when the given point A is without the circle, and the polar BC cuts it

3 To prove that the locus of the intersection of tangents drawn to a circle at the extremities of all chords which pass through a given point is the polar of that point.

Let A be the given point within the circle, of which O is the centre

Let HK be any chord passing through A ; and let the tangents at H and K intersect at P

it is required to prove that the locus of P is the polar of the point A

I. To shew that P lies on the polar of A .

Join OP cutting HK in Q

Join OA . and in OA produced take the point B ,

so that $OA \cdot OB = (\text{radius})^2$. II. 14

Then since A is fixed, B is also fixed

Join PB

Then since HK is the chord of contact of tangents from P,

$$\begin{array}{l} OP \cdot OQ = (\text{radius})^2 \quad \text{Ex 1 p 233.} \\ \text{But } OA \cdot OB = (\text{radius})^2, \\ OP \cdot OQ = OA \cdot OB \end{array} \quad \text{Constr}$$

the four points A, B, P, Q are concyclic
the \angle at Q and B together = two rt angles III 22

But the \angle at Q is a rt angle, Constr.
the \angle at B is a rt angle

And since the point B is the inverse of A, Constr

PB is the polar of A,

that is, the point P lies on the polar of A

II To shew that any point on the polar of A satisfies the given conditions

Let BC be the polar of A, and let P be any point on it Draw tangents PH, PK, and let HK be the chord of contact

Now from Ex 1, p 366, we know that the chord of contact HK is the polar of P,

and we also know that the polar of P must pass through A, for P is on BC, the polar of A Ex 2, p 367

that is, HK passes through A

P is the point of intersection of tangents drawn at the extremities of a chord passing through A

From I and II we conclude that the required locus is the polar of A

NOTE If A is *without* the circle, the theorem demonstrated in Part I of the above proof still holds good, but the converse theorem in Part II is not true for *all* points in BC For if A is *without* the circle, the polar BC will intersect it, and no point on that part of the polar which is *within* the circle can be the point of intersection of tangents

We now see that

(i) *The Polar of an external point with respect to a circle is the chord of contact of tangents drawn from it*

(ii) *The Polar of an internal point is the locus of the intersections of tangents drawn at the extremities of all chords which pass through it*

(iii) *The Polar of a point on the circumference is the tangent at that point*

The following theorem is known as the Harmonic Property of Pole and Polar

1 Any straight line drawn through a point is cut harmonically by the point, its polar, and the circumference of the circle.

Let AHB be a circle, P the given point and HK its polar, let Paqb be any straight line drawn through P meeting the polar at q and the C^{ce} of the circle at a and b.

then shall P, a, q, b be a harmonic range

In the case here considered, P is an external point

Join P to the centre O, and let PO cut the C^{ce} at A and B: let the polar of P cut the C^{ce} at H and K, and PO at Q.

Then PH is a tangent to the \odot AHB

Ex 1, p 366

From the similar triangles OPH, HPQ,

$$OP : PH = PH : PQ,$$

$$PQ \cdot PO = PH^2$$

$$= Pa \cdot Pb$$

the points O, Q, a, b are concyclic

$$\text{the } \angle aQA = \text{the } \angle abO$$

$$= \text{the } \angle ObQ$$

$$= \text{the } \angle OQb, \text{ in the same segment}$$

1 5

And since QH is perp to AB,

$$\text{the } \angle aQH = \text{the } \angle bQH$$

Qq and QP are the internal and external bisectors of the $\angle aQb$

P, a, q, b is a harmonic range Ex 1, p 360

The student should investigate for himself the case when P is an internal point.

Conversely, it may be shown that if through a fixed point P any secant is drawn cutting the circumference of a given circle at a and b, and if q is the harmonic conjugate at P with respect to a, b, then the locus of q is the polar of P with respect to the given circle

[For Examples on Pole and Polar, see p 370]

DEFINITION

A triangle so related to a circle that each side is the polar of the opposite vertex is said to be self-conjugate with respect to the circle

EXAMPLES ON POLE AND POLAR

- 1 The straight line which joins any two points is the polar with respect to a given circle of the point of intersection of their polars
- 2 The point of intersection of any two straight lines is the pole of the straight line which joins their poles
- 3 Find the locus of the poles of all straight lines which pass through a given point
- 4 Find the locus of the poles, with respect to a given circle, of tangents drawn to a concentric circle
- 5 If two circles cut one another orthogonally and PQ be any diameter of one of them, shew that the polar of P with regard to the other circle passes through Q .
- 6 If two circles cut one another orthogonally, the centre of each circle is the pole of their common chord with respect to the other circle
- 7 Any two points subtend at the centre of a circle an angle equal to one of the angles formed by the polars of the given points
- 8 O is the centre of a given circle, and AB a fixed straight line
 P is any point in AB , find the locus of the point inverse to P with respect to the circle
- 9 Given a circle, and a fixed point O on its circumference P is any point on the circle find the locus of the point inverse to P with respect to any circle whose centre is O
- 10 Given two points A and B , and a circle whose centre is O , shew that the rectangle contained by OA and the perpendicular from B on the polar of A is equal to the rectangle contained by OB and the perpendicular from A on the polar of B
- 11 Four points A, B, C, D are taken in order on the circumference of a circle, DA, CB intersect at P , AC, BD at Q and BA, CD in R shew that the triangle PQR is self-conjugate with respect to the circle
- 12 Give a linear construction for finding the polar of a given point with respect to a given circle Hence find a linear construction for drawing a tangent to a circle from an external point
- 13 If a triangle is self-conjugate with respect to a circle, the centre of the circle is at the orthocentre of the triangle
- 14 The polars, with respect to a given circle, of the four points of a harmonic range form a harmonic pencil and conversely

IV. ON THE RADICAL AXIS

1 To find the locus of points from which the tangents drawn to two given circles are equal

FIG 1

FIG 2

Let A and B be the centres of the given circles, whose radii are a and b , and let P be any point such that the tangent PQ drawn to the circle (A) is equal to the tangent PR drawn to the circle (B).

It is required to find the locus of P.

Join PA, PB, AQ, BR, AB, and from P draw PS perp to AB

Then because $PQ = PR$, $PQ^2 = PR^2$

But $PQ^2 = PA^2 - AQ^2$, and $PR^2 = PB^2 - BR^2$ 1 17

$PA^2 - AQ^2 = PB^2 - BR^2$;

that is, $PS^2 + AS^2 - a^2 = PS^2 + SB^2 - b^2$, 1 17

or, $AS^2 - a^2 = SB^2 - b^2$

Hence AB is divided at S, so that $AS^2 - SB^2 = a^2 - b^2$:

S is a fixed point.

Hence all points from which equal tangents can be drawn to the two circles lie on the straight line which cuts AB at rt angles, so that the difference of the squares on the segments of AB is equal to the difference of the squares on the radii

Again, by simply retracing these steps, it may be shewn that in Fig 1 every point in SP, and in Fig 2 every point in SP exterior to the circles, is such that tangents drawn from it to the two circles are equal

Hence we conclude that in Fig 1 the whole line SP is the required locus, and in Fig 2 that part of SP which is without the circles

In either case SP is said to be the **Radical Axis** of the two circles

COROLLARY If the circles cut one another as in Fig 2, it is clear that the Radical Axis is identical with the straight line which passes through the points of intersection of the circles, for it follows readily from III 36 that tangents drawn to two intersecting circles from any point in the common chord produced are equal

2 The Radical Axes of three circles taken in pairs are concurrent

Let there be three circles whose centres are A, B, C

Let OZ be the radical axis of the \odot (A) and (B), and OY the Radical Axis of the \odot (A) and (C), O being the point of their intersection

then shall the radical axis of the \odot (B) and (C) pass through O

It will be found that the point O is either without or within all the circles

I When O is without the circles

From O draw OP, OQ, OR tangents to the \odot (A), (B), (C)

Then because O is a point on the radical axis of (A) and (B), *Hyp*
 $OP = OQ$

And because O is a point on the radical axis of (A) and (C), *Hyp*
 $OP = OR,$
 $OQ = OR,$

O is a point on the radical axis of (B) and (C),
 i.e. the radical axis of (B) and (C) passes through O

II If the circles intersect in such a way that O is within them all, the radical axes are then the common chords of the three circles taken two and two, and it is required to prove that these common chords are concurrent This may be shewn indirectly by III 35

DEFINITION The point of intersection of the radical axes of three circles taken in pairs is called the radical centre

8 To draw the radical axis of two given circles.

Let A and B be the centres of the given circles
it is required to draw their radical axis

If the given circles intersect, then the st. line drawn through their points of intersection will be the radical axis [Ex 1, Cor. p. 372]

But if the given circles do not intersect,
describe any circle so as to cut them in E, F and G, H.

Join EF and HG, and produce them to meet in P

Join AB, and from P draw PS perp to AB.

Then PS shall be the radical axis of the C^s (A), (B)

DEFINITION. If each pair of circles in a given system have the same radical axis, the circles are said to be co-axal.

EXAMPLES

1. Shew that the radical axis of two circles bisects any one of their common tangents

2. If tangents are drawn to two circles from any point on their radical axis, shew that a circle described with this point as centre and any one of the tangents as radius, cuts both the given circles orthogonally

3 O is the radical centre of three circles, and from O a tangent OT is drawn to any one of them. shew that a circle whose centre is O and radius OT cuts all the given circles orthogonally

4 If three circles touch one another, taken two and two, shew that their common tangents at the points of contact are concurrent

5 If circles are described on the three sides of a triangle as diameter, their radical centre is the orthocentre of the triangle

6 All circles which pass through a fixed point and cut a given circle orthogonally, pass through a second fixed point

7 Find the locus of the centres of all circles which pass through a given point and cut a given circle orthogonally

8 Describe a circle to pass through two given points and cut a given circle orthogonally

9 Find the locus of the centres of all circles which cut two given circles orthogonally

10 Describe a circle to pass through a given point and cut two given circles orthogonally

11 The difference of the squares on the tangents drawn from any point to two circles is equal to twice the rectangle contained by the straight line joining their centres and the perpendicular from the given point on their radical axis

12 In a system of co axial circles which do not intersect, any point is taken on the radical axis, shew that a circle described from this point as centre with radius equal to the tangent drawn from it to any one of the circles, will meet the line of centres in two fixed points

[These fixed points are called the Limiting Points of the system]

13 In a system of co-axial circles the two limiting points and the points in which any one circle of the system cuts the line of centres form a harmonic range

14 In a system of co-axial circles a limiting point has the same polar with regard to all the circles of the system

15 If two circles are orthogonal any diameter of one is cut harmonically by the other

Obs In the two following theorems we are to suppose that the segments of straight lines are expressed numerically in terms of some common unit, and the ratio of one such segment to another will be denoted by the fraction of which the first is the numerator and the second the denominator

V ON TRANSVERALS

DEFINITION. A straight line drawn to cut a given system of lines is called a **transversal**

1. *If three concurrent straight lines are drawn from the angular points of a triangle to meet the opposite sides, then the product of three alternate segments taken in order is equal to the product of the other three segments*

Let AD, BE, CF be drawn from the vertices of the $\triangle ABC$ to intersect at O, and cut the opposite sides at D, E, F then shall $BD \cdot CE \cdot AF = DC \cdot EA \cdot FB$

By similar triangles it may be shown that

$BD \cdot DC = \text{the alt. of } \triangle AOB \cdot \text{the alt. of } \triangle AOC,$

$$\frac{BD}{DC} = \frac{\triangle AOB}{\triangle AOC},$$

similarly,

$$\frac{CE}{EA} = \frac{\triangle BOC}{\triangle BOA},$$

and

$$\frac{AF}{FB} = \frac{\triangle COA}{\triangle COB}.$$

Multiplying these ratios, we have

$$\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = 1,$$

or,

$$BD \cdot CE \cdot AF = DC \cdot EA \cdot FB$$

Q. E. D.

The converse of this theorem, which may be proved inductively, is very important. it may be enunciated thus:

If three straight lines drawn from the vertices of a triangle cut the opposite sides so that the product of three alternate segments taken in order is equal to the product of the other three, then the three straight lines are concurrent

That is, if $BD \cdot CE \cdot AF = DC \cdot EA \cdot FB$,
then AD, BE, CF are concurrent

2 If a transversal is drawn to cut the sides, or the sides produced, of a triangle, the product of three alternate segments taken in order is equal to the product of the other three segments

Let ABC be a triangle, and let a transversal meet the sides BC, CA, AB, or these sides produced, at D, E, F
then shall $BD \cdot CE \cdot AF = DC \cdot EA \cdot FB$

Draw AH par^l to BC, meeting the transversal at H

Then from the similar $\triangle DBF, HAF,$

$$\frac{BD}{FB} = \frac{HA}{AF}$$

and from the similar $\triangle DOE, HAE,$

$$\frac{CE}{DC} = \frac{EA}{HA}$$

, by multiplication, $\frac{BD}{FB} \cdot \frac{CE}{DC} = \frac{EA}{AF},$

that is, $\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = 1,$

or, $BD \cdot CE \cdot AF = DC \cdot EA \cdot FB$

Q E D

NOTE In this theorem the transversal must either meet two sides and the third side produced, as in Fig 1, or all three sides produced, as in Fig 2

The converse of this Theorem may be proved indirectly.

If three points are taken in two sides of a triangle and the third side produced, or in all three sides produced, so that the product of three alternate segments taken in order is equal to the product of the other three segments, the three points are collinear

The propositions given on pages 103—106 relating to the concurrence of straight lines in a triangle, may be proved by the method of transversals, and in addition to these the following important theorems may be established

DEFINITIONS

(i) If two triangles are such that three straight lines joining corresponding vertices are concurrent, they are said to be co-polar.

(ii) If two triangles are such that the points of intersection of corresponding sides are collinear, they are said to be co-axial.

THEOREMS TO BE PROVED BY TRANSVERSALS

1. *The straight lines which join the vertices of a triangle to the points of contact of the inscribed circle (or any of the three inscribed circles) are concurrent.*

2. *The middle points of the diagonals of a complete quadrilateral are collinear.*

3. *Co-polar triangles are also co-axial, and conversely co-axial triangles are also co-polar.*

4. *The six centres of similitude of three circles lie three by three on four straight lines.*

MISCELLANEOUS EXAMPLES ON BOOK VI

1. Through D, any point in the base of a triangle ABC, straight lines DE, DF are drawn parallel to the sides AB, AC, and meeting the sides at E, F. shew that the triangle AEF is a mean proportional between the triangles FBD, EDC.

2. If two triangles have one angle of the one equal to one angle of the other, and a second angle of the one supplementary to a second angle of the other, then the sides about the third angles are proportional.

3. AE bisects the vertical angle of the triangle ABC and meets the base in E, shew that if circles are described about the triangles ABE, ACE, the diameters of these circles are to each other in the same ratio as the segments of the base.

4. Through a fixed point O draw a straight line so that the parts intercepted between O and the perpendiculars drawn to the straight line from two other fixed points may have a given ratio.

5 The angle A of a triangle ABC is bisected by AD meeting BC in D, and AX is the median bisecting BC shew that XD has the same ratio to XB as the difference of the sides has to their sum

6 AD and AE bisect the vertical angle of a triangle internally and externally, meeting the base in D and E, shew that if O is the middle point of BC, then OB is a mean proportional between OD and OE

7 P and Q are fixed points, AB and CD are fixed parallel straight lines; any straight line is drawn from P to meet AB at M, and a straight line is drawn from Q parallel to PM meeting CD at N shew that the ratio of PM to QN is constant, and thence shew that the straight line through M and N passes through a fixed point

8 C is the middle point of an arc of a circle whose chord is AB, D is any point in the conjugate arc shew that

$$AD + DB \cdot DC = AB \cdot AC$$

9 In the triangle ABC the side AC is double of BC If CD, CE bisect the angle ACB internally and externally meeting AB in D and E, shew that the areas of the triangles CBD, ACD, ABC, CDE are as 1, 2, 3, 4

10 AB, AC are two chords of a circle, a line parallel to the tangent at A cuts AB, AC in D and E respectively shew that the rectangle AB, AD is equal to the rectangle AC, AE

11 If from any point on the hypotenuse of a right-angled triangle perpendiculars are drawn to the two sides, the rectangle contained by the segments of the hypotenuse will be equal to the sum of the rectangles contained by the segments of the sides

12 D is a point in the side AC of the triangle ABC, and E is a point in AB If BD, CE divide each other into parts in the ratio 1 1, then D, E divide CA, BA in the ratio 3 1.

13 If the perpendiculars from two fixed points on a straight line passing between them be in a given ratio, the straight line must pass through a third fixed point

14 PA, PB are two tangents to a circle, PCD any chord through P shew that the rectangle contained by one pair of opposite sides of the quadrilateral ACBD is equal to the rectangle contained by the other pair

15 A, B, C are any three points on a circle, and the tangent at A meets BC produced in D shew that the diameters of the circles circumscribed about ABD, ACD are as AD to CD

16 AB, CD are two diameters of the circle ADBC at right angles to each other, and EF is any chord, CE, CF are drawn meeting AB produced in G and H prove that the rect CE, HG = the rect EF, CH

17 From the vertex A of any triangle ABC draw a line meeting BC produced in D so that AD may be a mean proportional between the segments of the base

18 Two circles touch internally at O, AB a chord of the larger circle touches the smaller in C which is cut by the lines OA, OB in the points P, Q shew that $OP \cdot OQ = AC \cdot CB$

19 AB is any chord of a circle, AC, BC are drawn to any point C in the circumference and meet the diameter perpendicular to AB at D, E if O be the centre, shew that the rect OD, OE is equal to the square on the radius

20 YD is a tangent to a circle drawn from a point Y in the diameter AB produced, from D a perpendicular DX is drawn to the diameter shew that the points X, Y divide AB internally and externally in the same ratio

21 Determine a point in the circumference of a circle, from which lines drawn to two other given points shall have a given ratio

22 O is the centre and OA a radius of a given circle, and V is the middle point of OA, P and Q are two points on the circumference on opposite sides of A and equidistant from it, QV is produced to meet the circle in L shew that, whatever be the length of the arc PQ, the chord LP will always meet OA produced in a fixed point.

23 EA, EA' are diameters of two circles touching each other externally at E, a chord AB of the former circle, when produced, touches the latter at C', while a chord A'B of the latter touches the former at C prove that the rectangle, contained by AB and A'B', is four times as great as that contained by BC' and B'C

24 If a circle be described touching externally two given circles, the straight line passing through the points of contact will intersect the line of centres of the given circles at a fixed point.

25 Two circles touch externally in C, if any point D be taken without them so that the radii AC, BC subtend equal angles at D, and DE, DF be tangents to the circles, shew that DC is a mean proportional between DE and DF.

26. If through the middle point of the base of a triangle any line be drawn intersecting one side of the triangle, the other produced, and the line drawn parallel to the base from the vertex, it will be divided harmonically

27. If from either base angle of a triangle a line be drawn intersecting the median from the vertex, the opposite side, and the line drawn parallel to the base from the vertex, it will be divided harmonically

28. Any straight line drawn to cut the arms of an angle and its internal and external bisectors is cut harmonically

29. P, Q are harmonic conjugates of A and B, and C is an external point. If the angle PCQ is a right angle, shew that CP, CQ are the internal and external bisectors of the angle ACB

30. From C, one of the base angles of a triangle, draw a straight line meeting AB in G, and a straight line through A parallel to the base in E, so that CE may be to EG in a given ratio

31. P is a given point outside the angle formed by two given lines AB, AC. Shew how to draw a straight line from P such that the parts of it intercepted between P and the lines AB, AC may have a given ratio

32. Through a given point within a given circle, draw a straight line such that the parts of it intercepted between that point and the circumference may have a given ratio. How many solutions does the problem admit of?

33. If a common tangent be drawn to any number of circles which touch each other internally, and from any point of this tangent as a centre a circle be described, cutting the other circles, and if from this centre lines be drawn through the intersections of the circles, the segments of the lines within each circle shall be equal

34. APB is a quadrant of a circle, SPT a line touching it at P, C is the centre, and PM is perpendicular to CA. Prove that
the $\triangle SCT$ the $\triangle ACB$ the $\triangle ACB$ the $\triangle CMP$

35. ABC is a triangle inscribed in a circle, AD, AE are lines drawn to the base BC parallel to the tangents at B, C respectively, shew that $AD=AE$, and $BD \cdot CE = AB^2 \cdot AC^2$

36. AB is the diameter of a circle, E the middle point of the radius OB, on AE, EB as diameters circles are described, PQL is a common tangent meeting the circles at P and Q, and AB produced at L. Shew that BL is equal to the radius of the smaller circle

37. The vertical angle C of a triangle is bisected by a straight line which meets the base at D, and is produced to a point E, such that the rectangle contained by CD and CE is equal to the rectangle contained by AC and CB shew that if the base and vertical angle be given, the position of E is invariable

38 ABC is an isosceles triangle having the base angles at B and C each double of the vertical angle if BE and CD bisect the base angles and meet the opposite sides in E and D, shew that DE divides the triangle into figures whose ratio is equal to that of AB to BC

39 If AB, the diameter of a semicircle, be bisected in C and on AC and CB circles be described, and in the space between the three circumferences a circle be inscribed, shew that its diameter will be to that of the equal circles in the ratio of two to three.

40 O is the centre of a circle inscribed in a quadrilateral ABCD, a line EOF is drawn and making equal angles with AD and BC, and meeting them in E and F respectively shew that the triangles AEO, BOF are similar, and that

$$AE \cdot ED = CF \cdot FB$$

41 From the last exercise deduce the following The inscribed circle of a triangle ABC touches AB in F, XOY is drawn through the centre making equal angles with AB and AC, and meeting them in X and Y respectively shew that BX XF = AY YC

42 Inscribe a square in a given semicircle

43 Inscribe a square in a given segment of a circle

44 Describe an equilateral triangle equal to a given isosceles triangle

45 Describe a square having given the difference between a diagonal and a side

46 Given the vertical angle, the ratio of the sides containing it, and the diameter of the circumscribing circle, construct the triangle

47. Given the vertical angle, the line bisecting the base, and the angle the bisector makes with the base, construct the triangle

48 In a given circle inscribe a triangle so that two sides may pass through two given points and the third side be parallel to a given straight line

49 In a given circle inscribe a triangle so that the sides may pass through three given points

50 A, B, X, Y are four points in a straight line, and O is such a point in it that the rectangle OA, OB is equal to the rectangle OX, OY. If a circle be described with centre O and radius equal to a mean proportional between OA and OB, shew that at every point on this circle AB and XY will subtend equal angles

51 O is a fixed point, and OP is any line drawn to meet a fixed straight line in P, if on OP a point Q is taken so that OQ to OP is a constant ratio, find the locus of Q

52 O is a fixed point, and OP is any line drawn to meet the circumference of a fixed circle in P, if on OP a point Q is taken so that OQ to OP is a constant ratio, find the locus of Q

53 If from a given point two straight lines are drawn including a given angle, and having a fixed ratio, find the locus of the extremity of one of them when the extremity of the other lies on a fixed straight line

54 On a straight line PAB, two points A and B are marked and the line PAB is made to revolve round the fixed extremity P. C is a fixed point in the plane in which PAB revolves, prove that if CA and CB be joined and the parallelogram CADB be completed, the locus of D will be a circle

55 Find the locus of a point whose distances from two fixed points are in a given ratio

56 Find the locus of a point from which two given circles subtend the same angle

57 Find the locus of a point such that its distances from two intersecting straight lines are in a given ratio.

58 In the figure on page 364, shew that QT, P'T' meet on the radical axis of the two circles

59 Through two given points draw a circle cutting another circle so that their common chord may be equal to a given straight line

60 ABC is any triangle, and on its sides equilateral triangles are described externally. If X, Y, Z are the centres of their inscribed circles, shew that the triangle XYZ is equilateral

A TEXT BOOK OF EUCLID'S ELEMENTS,

including Alternative Proofs, together with additional Theorems and Exercises, classified and arranged By H S HALL, M A., and F H STEVENS, M A., Masters of the Military and Engineering Side, Clifton College Globe 8vo. Book I 1s Books I and II 1s. 6d Books I—IV. 3s. Books III—VI 3s Books I—VI. 4s 6d

Nature says —“We have here the completion of a work which in its first instalment (Books I. and II.) has already won a considerable amount of favourable notice from teachers The ‘end’ has ‘crowned the work’ in a similar satisfactory manner, and, without entering into any ‘odious’ comparisons with recent like editions, we consider this to be abreast of the best Great attention has been paid to the arrangement and composition of the text, and the difficulties which delay beginners have been carefully smoothed and explained In conclusion, we need only say the work before us contains all that is needful to a student, who, if he has this, will require no other text-book to become an expert geometer—i. e. in so far as outside aid can make one ”

The *Journal of Education* says —“Most teachers are already familiar with the authors’ edition of the first two books of Euclid, which forms Part I of this volume, and it is hardly necessary to say more than that the same plan has been followed in the Second Part The additional theorems, placed at the end of each book, make the work the most complete introduction to Plane Geometry based on Euclid’s Elements that we have yet seen ”

The *Guardian* says —“In this excellent text-book for schools Euclid’s proofs have been for the most part adhered to, and in the few deviations that have been made, where difficulties usually present themselves to the student, the matter substituted is characterised by clearness and simplicity.”

The *Athenæum* says —“The work will be received with favour by practical teachers ”

The *Cambridge Review* says —“To teachers and students alike we can heartily recommend this little edition of Euclid’s Elements The proofs of Euclid are with very few exceptions retained, but the unnecessarily complicated expression is avoided, and the steps of the proofs are so arranged as readily to catch the eye Prop 10, Book IV, is a good example of how a long proposition ought to be written out The candidate for mathematical honours will find introduced in their proper places short sketches of such subjects as the Pedal Line, Maxima and Minima, Harmonic Division, Concurrent Lines, &c, quite enough of each for all ordinary requirements Useful notes and easy examples are scattered throughout each book, and sets of hard examples are given at the end The whole is so evidently the work of practical teachers, that we feel sure it must soon displace every other Euclid ”

The *Journal of Education* says —“The most complete introduction to Plane Geometry based on Euclid’s Elements that we have yet seen ”

The *Practical Teacher* says —“One of the most attractive books on Geometry that has yet fallen into our hands ”

Works by Messrs Hall and Stevens—continued.

The *Literary World* says —“A distinct advance on all previous editions ”

The *Irish Teachers' Journal* says —“It must rank as one of the very best editions of Euclid in the language ”

EUCLID BOOK XI Propositions 1—21, with Alternative Proofs, Exercises, and Additional Theorems and Examples

ELEMENTARY MENSURATION, WITH EXERCISES IN THE MENSURATION OF PLANE AND SOLID FIGURES Globe 8vo [In the Press]

MACMILLAN AND CO, LONDON

Works by H S HALL, M.A., formerly Scholar of Christ's College, Cambridge, Master of the Military and Engineering Side, Clifton College, and S R KNIGHT, B.A., formerly Scholar of Trinity College, Cambridge, late Assistant Master at Marlborough College

ELEMENTARY ALGEBRA FOR SCHOOLS.

Fourth Edition Revised and enlarged Globe 8vo (bound in maroon coloured cloth), 3s 6d With Answers (bound in green coloured cloth), 4s 6d

PREFACE TO THE FOURTH EDITION

In the Second Edition a chapter on the Theory of Quadratic Equations was introduced, the book is now further enlarged by the addition of chapters on Permutations and Combinations, the Binomial Theorem, Logarithms, and Scales of Notation These have been abridged from our *Higher Algebra*, to which readers are referred for a fuller and more exhaustive treatment The very favourable reception accorded to the first three editions leads us to hope that in its present more complete form the work will be found suitable as a first text-book for every class of student, and amply sufficient for all whose study of Algebra does not extend beyond the Binomial Theorem

The *Schoolmaster* says “Has so many points of excellence, as compared with its predecessors, that no apology is needed for its issue

The plan always adopted by every good teacher of frequently recapitulating and making additions at every recapitulation, is well carried out ”

The *Educational Times* says —“ A very good book The explanations are concise and clear, and the examples both numerous and well chosen ”

Works by Messrs Hall and Knight—continued

Nature says—"This is, in our opinion, the best Elementary Algebra for school use. We confidently recommend it to mathematical teachers, who, we feel sure, will find it the best book of its kind for teaching purposes."

The *Academy* says—"Buy or borrow the book for yourselves and judge, or write a better. A higher text-book is on its way. This occupies sufficient ground for the generality of boys."

HIGHER ALGEBRA. A Sequel to "Elementary Algebra for Schools" Third Edition, revised. Crown 8vo 7s 6d

The *Athenæum* says—"The *Elementary Algebra* by the same authors, which has already reached a third edition, is a work of such exceptional merit that those acquainted with it will form high expectations of the sequel to it now issued. Nor will they be disappointed. Of the authors' *Higher Algebra*, as of their *Elementary Algebra*, we unhesitatingly assert that it is by far the best work of its kind with which we are acquainted. It supplies a want much felt by teachers."

The *Academy* says—"Is as admirably adapted for College students as its predecessor was for schools. It is a well arranged and well-reasoned-out treatise, and contains much that we have not met with before in similar works. For instance, we note as specially good the articles on Convergency and Divergency of Series, on the treatment of Series generally, and the treatment of Continued Fractions. The book is almost indispensable and will be found to improve upon acquaintance."

The *Saturday Review* says—"They have presented such difficult parts of the subject as Convergency and Divergency of Series, Series generally, and Probability with great clearness and fulness of detail. No student preparing for the University should omit to get this work in addition to any other he may have, for he need not fear to find here a mere repetition of the old story. We have found much matter of interest and many valuable hints. We would specially note the examples, of which there are enough, and more than enough, to try any student's powers."

ALGEBRAICAL EXERCISES AND EXAMINATION PAPERS. To accompany "Elementary Algebra" Third Edition. Globe 8vo 2s 6d

The *Schoolmaster* says—"As useful a collection of examination papers in algebra as we ever met with. Each 'exercise' is calculated to occupy about an hour in its solution. Besides these, there are 35 examination papers set at various competitive examinations during the last three years. The answers are at the end of the book. We can strongly recommend the volume to teachers seeking a well-arranged series of tests in algebra."

The *Educational Times* says—"It is only a few months since we spoke in high praise of an Elementary Algebra by the same authors of the above papers. We can speak also in high praise about this little book. It consists of over a hundred progressive miscellaneous exercises, followed by a collection of papers set at recent examinations."

Works by Messrs Hall and Knight—continued

The exercises are timed, as a rule, to take an hour. Messrs Hall and Knight have had plenty of experience, and have put that experience to good use."

The *Spectator* says—"The papers are arranged for about an hour's work, and will be found a useful addition to the school text-book."

The *Irish Teachers' Journal* says—"We know of no better work to place in the hands of junior teachers, monitors, and senior pupils. Any person who works carefully and steadily through this book could not possibly fail in an examination of Elementary Algebra. We congratulate the authors on the skill displayed in the selection of examples."

ARITHMETICAL EXERCISES AND EXAMINATION PAPERS With an Appendix containing Questions in Logarithms and Mensuration. Second Edition, revised and enlarged. Globe 8vo 2s 6d

The *Cambridge Review* says—"All the mathematical work these gentlemen have given to the public is of genuine worth, and these exercises are no exception to the rule. The addition of the logarithm and mensuration questions add greatly to their value."

Nature says—"In this book we have a collection of examples comprising about eighty progressive miscellaneous exercises and a set of fifty papers taken from such examinations as the London University, Oxford and Cambridge Local, Cambridge Previous, Army Preliminary, etc. The examples are judiciously chosen, and great care seems to have been taken to make the work as progressive as possible. An appendix is added, consisting of two hundred graduated questions in logarithms and mensuration, preceded by a list of the numerical constants and formulæ used in the latter. The answers to the examples are all collected together at the end."

The *Literary World* says—"In *Arithmetical Exercises and Examination Papers*, Mr Hall and Mr Knight have followed the plan adopted in their *Algebraical Exercises and Examination Papers*. The exercises, each containing eight questions, are eighty in number, and are divided into six groups. Each group includes examples in rules beyond those given in the preceding one, as well as somewhat harder examples in the rules previously represented. The examples seem well chosen, and, on the whole, carefully graduated."

The *Scotsman* says—"The exercises and questions are well selected, and form an excellent book of discipline in arithmetic. An appendix of questions in logarithms and mensuration adds to the value of the work."

The *School Board Chronicle* says—"The work cannot fail to be of immense utility."

The *Educational Times* says—"As a preparation for examination the book will be found of the utmost value."
